

Logarithmic intersections of double ramification cycles

David Holmes and Rosa Schwarz

ABSTRACT

We describe a theory of logarithmic Chow rings and tautological subrings for logarithmically smooth algebraic stacks, via a generalisation of the notion of piecewise-polynomial functions. Using this machinery we prove that the double-double ramification cycle lies in the tautological subring of the (classical) Chow ring of the moduli space of curves and that the logarithmic double ramification cycle is divisorial (as conjectured by Molcho, Pandharipande, and Schmitt).

1. Introduction

If C/S is a family of smooth algebraic curves and $\mathcal{L}$ on C a line bundle, the double ramification cycle measures the locus of points $s \in S$ where the line bundle $\mathcal{L}$ becomes trivial upon restriction to the fibre C_s . More formally, $\mathrm{DR}(\mathcal{L})$ is a virtual fundamental class of this locus, living in the Chow group of codimension g cycles on S . Extending this class in a natural way to families of (pre)stable curves, and giving a tautological formula, has been the subject of much recent research, including [FP05, Hai13, GZ14, Dud18, FP18, Sch18, JPPZ17, MW20, JPPZ20, HKP18, Hol21, HS21, HPS19]. In particular, [BHP⁺20] gives a definition of a double ramification cycle $\mathrm{DR}(\mathcal{L})$ for any line bundle $\mathcal{L}$ on any family C/S of prestable curves and proves a tautological formula for this cycle.

1.1 Double-double ramification cycles are tautological

Now suppose that we have two line bundles $\mathcal{L}_1, \mathcal{L}_2$ on a smooth curve C/S . Then the *double-double ramification cycle* $\mathrm{DR}(\mathcal{L}_1, \mathcal{L}_2)$ measures the locus of $s \in S$ such that both $\mathcal{L}_1$ and $\mathcal{L}_2$ become trivial on the fibre C_s – of course, this is just the intersection of the corresponding cycles $\mathrm{DR}(\mathcal{L}_1)$ and $\mathrm{DR}(\mathcal{L}_2)$. The key insight of [HPS19] was that this naive intersection is the ‘wrong’ way to extend this class to a family of (pre)stable curves. Instead, one should construct a new virtual class $\mathrm{DR}(\mathcal{L}_1, \mathcal{L}_2)$ for the product (see Section 1.2 below), and in general it will not equal the product of the virtual classes of the two factors:

$$\mathrm{DR}(\mathcal{L}_1, \mathcal{L}_2) \neq \mathrm{DR}(\mathcal{L}_1) \cdot \mathrm{DR}(\mathcal{L}_2).$$

Why is this new construction better than simply taking the intersection of the classes? One way to see this is to consider what happens when one tensors the line bundles $\mathcal{L}_1$ and $\mathcal{L}_2$ together. For a family of smooth curves, one sees easily the formula

$$\mathrm{DR}(\mathcal{L}_1)\mathrm{DR}(\mathcal{L}_2) = \mathrm{DR}(\mathcal{L}_1)\mathrm{DR}(\mathcal{L}_1 \otimes \mathcal{L}_2); \quad (1.1.1)$$

this also holds in compact type, which plays a key role in the construction of quadratic double ramification integrals and the noncommutative Korteweg–de Vries (KdV) hierarchy in [BR21]. However, (1.1.1) *fails* for general families of (pre)stable curves, obstructing the extension of quadratic double ramification integrals beyond the compact-type case (see [HPS19, § 8] for an explicit example of this failure). On the other hand, the formula

$$\mathrm{DR}(\mathcal{L}_1, \mathcal{L}_2) = \mathrm{DR}(\mathcal{L}_1, \mathcal{L}_1 \otimes \mathcal{L}_2) \quad (1.1.2)$$

does hold for arbitrary families, giving hope of extending the results of [BR21] beyond compact type. This is a particular instance of a $\mathrm{GL}_2(\mathbb{Z})$ -invariance property for the double-double ramification cycles, which we generalise in Theorem 5.7 to $\mathrm{GL}_r(\mathbb{Z})$ -invariance for r -fold products.

While the cycle $\mathrm{DR}(\mathcal{L}_1, \mathcal{L}_2)$ is in some ways better behaved than the product $\mathrm{DR}(\mathcal{L}_1)\mathrm{DR}(\mathcal{L}_2)$, until now the question of whether it is a tautological cycle has remained open and is important to address if we hope to study quadratic double ramification integrals. Our first main theorem resolves this question.

THEOREM 1.1. *Let g, n be non-negative integers, r a positive integer, and $\mathcal{L}_1, \dots, \mathcal{L}_r$ line bundles on the universal curve over $\overline{\mathcal{M}}_{g,n}$. Then the r -fold double ramification cycle*

$$\mathrm{DR}(\mathcal{L}_1, \dots, \mathcal{L}_r) \quad (1.1.3)$$

lies in the tautological subring of the Chow ring of $\overline{\mathcal{M}}_{g,n}$.

This theorem opens up the possibility of giving an explicit formula for the class $\mathrm{DR}(\mathcal{L}_1, \dots, \mathcal{L}_r)$ in terms of the standard generators of the tautological ring, as was done in [JPPZ17] for the case $r = 1$ (that $\mathrm{DR}(\mathcal{L})$ lies in the tautological ring was proven earlier by Faber and Pandharipande [FP05], but no formula was given at that time).

Remark 1.2. Ranganathan and Molcho have an independent approach to Theorem 1.1, by studying the virtual strict transforms of the DR cycle; see [MR21].

1.2 Logarithmic Chow rings

The fundamental reason for the failure of the product formula (1.1.1) for stable curves is that $\mathrm{DR}(\mathcal{L})$ should not really be viewed as a cycle on $\overline{\mathcal{M}}_{g,n}$, but rather it lives naturally on a *log blowup* of $\overline{\mathcal{M}}_{g,n}$ – essentially an iterated blowup in boundary strata. To avoid having to make a choice of blowup, we work in $\mathrm{LogCH}(\overline{\mathcal{M}}_{g,n})$, which is defined to be the colimit of the Chow rings of all log blowups of $\overline{\mathcal{M}}_{g,n}$. This logarithmic Chow ring comes with a proper pushforward $\nu_*: \mathrm{LogCH}(\overline{\mathcal{M}}_{g,n}) \rightarrow \mathrm{CH}(\overline{\mathcal{M}}_{g,n})$ to the usual Chow ring, which is a group homomorphism but *not* a ring homomorphism. The construction of $\mathrm{DR}(\mathcal{L})$ can be upgraded (see Definition 4.5) to give a cycle $\mathrm{LogDR}(\mathcal{L}) \in \mathrm{LogCH}(\overline{\mathcal{M}}_{g,n})$, whose pushforward to $\mathrm{CH}(\overline{\mathcal{M}}_{g,n})$ is $\mathrm{DR}(\mathcal{L})$. The formula

$$\mathrm{LogDR}(\mathcal{L}_1)\mathrm{LogDR}(\mathcal{L}_2) = \mathrm{LogDR}(\mathcal{L}_1)\mathrm{LogDR}(\mathcal{L}_1 \otimes \mathcal{L}_2)$$

is not hard to prove in $\mathrm{LogCH}(\overline{\mathcal{M}}_{g,n})$ (see Theorem 5.7). We then define

$$\mathrm{DR}(\mathcal{L}_1, \dots, \mathcal{L}_r) = \nu_*(\mathrm{LogDR}(\mathcal{L}_1) \cdots \mathrm{LogDR}(\mathcal{L}_r)),$$

from which the product formula (1.1.2) is immediate. The fact that (1.1.1) fails is then just a symptom of the fact that the proper pushforward $\nu_*: \text{LogCH}(\overline{\mathcal{M}}_{g,n}) \rightarrow \text{CH}(\overline{\mathcal{M}}_{g,n})$ is not a ring homomorphism.

1.3 Logarithmic tautological rings

Our proof of Theorem 1.1 (that double-double ramification cycles are tautological) will run via showing that $\text{LogDR}(\mathcal{L})$ is tautological; but first we have to decide what it means for a cycle in $\text{LogCH}(\overline{\mathcal{M}}_{g,n})$ to be tautological.

In fact, we need to do something slightly more general. Our proof that $\text{LogDR}(\mathcal{L})$ is tautological for a line bundle $\mathcal{L}$ on the universal curve over $\overline{\mathcal{M}}_{g,n}$ proceeds by reduction to the fact that the usual double ramification cycle is tautological. However, for this reduction step it will be necessary to modify the universal curve (so that it is no longer stable, only prestable) and also to modify the line bundle $\mathcal{L}$. This leads us to study double ramification cycles on the total-degree-0¹ Picard stack $\mathfrak{Jac}$ of the universal curve over the stack $\mathfrak{M}$ of all prestable marked curves, exactly the setting considered in [BHP⁺20].

It is then necessary to define a tautological subring of $\text{LogCH}(\mathfrak{Jac})$, which is slightly delicate as this smooth algebraic stack is neither Deligne–Mumford nor quasi-compact. For this we develop a theory of piecewise-polynomial functions on any log algebraic stack, and for log smooth stacks over a field or Dedekind scheme, we construct a map from the space of piecewise-polynomial functions to the log Chow ring. We then define the tautological subring as the ring generated by the image of this map together with pullbacks of classes in the usual tautological ring on $\mathfrak{Jac}$ (as described in [BHP⁺20, Definition 4]). This leads to our main technical result, from which Theorem 1.1 follows easily.

THEOREM 1.3. *The cycle LogDR lies in the tautological subring of $\text{LogCH}(\mathfrak{Jac})$.*

In fact we prove a stronger result (Corollary 4.21). If $\mathcal{L}$ is the tautological line bundle on the universal prestable curve $\pi: C \rightarrow \mathfrak{Jac}$, we define the class

$$\eta = \pi_*(c_1(\mathcal{L})^2) \in \text{CH}(\mathfrak{Jac})$$

and prove that LogDR lies in the subring of $\text{LogCH}(\mathfrak{Jac})$ generated by boundary divisors and the class η .

1.4 LogDR is divisorial

Double ramification cycles in logarithmic Chow rings are also studied in the recent paper [MPS21], with a particular emphasis on the case where $\mathcal{L}$ is the trivial bundle (corresponding to the top Chern class of the Hodge bundle on the moduli space of curves). The objective there is to understand the complexity of $\text{DR}(\mathcal{O}_C)$ in the Chow ring, in particular to understand when it can be written as a polynomial in divisor classes. It is shown that $\text{DR}(\mathcal{O}_C)$ cannot be written as a polynomial in divisor classes and conjectured that $\text{LogDR}(\mathcal{L})$ can be written as a polynomial in divisors for all $\mathcal{L}$. As a byproduct of the proof of Theorem 1.3, we obtain something a little more general. The ring $\text{LogCH}(\mathfrak{Jac})$ is graded by codimension, and we write $\text{divLogCH}(\mathfrak{Jac})$ for the subring generated in degree 1. Since LogDR lies in the ring generated by η and boundary divisors, we immediately obtain the following result.

¹The authors of [BHP⁺20] do not assume total degree 0, but the double ramification cycle is supported in total degree 0, so this is only a superficial change.

 FIGURE 1. Curve over $\overline{\mathcal{M}}_{1,2}$

 FIGURE 2. $\widetilde{\mathcal{M}}_{1,2} \rightarrow \overline{\mathcal{M}}_{1,2}$

THEOREM 1.4. $\text{LogDR} \in \text{divLogCH}(\mathfrak{Jac})$.

By pulling back to $\overline{\mathcal{M}}_{g,n}$, this proves [MPS21, Conjecture C].

1.5 Strategy of proof

Our strategy is best illustrated by carrying it out over $\overline{\mathcal{M}}_{1,2}$. We write C for the universal curve with markings p_1, p_2 , and we let $\mathcal{L} = \mathcal{O}(2p_1 - 2p_2)$. Then $\text{DR}(\mathcal{L})$ is invariant under various changes to $\mathcal{L}$; these are listed quite exhaustively in [BHP⁺20, § 0.6]. In particular, let D be the prime divisor on C given by the rational tails (via the isomorphism $C = \overline{\mathcal{M}}_{1,3}$ this is the closure of the locus of curves with a single rational tail and all markings on the tail). Then Invariance V of [BHP⁺20, § 0.6] states that

$$\text{DR}(\mathcal{L}) = \text{DR}(\mathcal{L}(D)).$$

Our toehold on LogDR is obtained by realising that it should satisfy a stronger invariance property, corresponding to twisting by vertical divisors which only exist after blowing up $\overline{\mathcal{M}}_{1,2}$. Let $x \in \overline{\mathcal{M}}_{1,2}$ be the 2-marked 2-gon (Figure 1), and let $\widetilde{\mathcal{M}}_{1,2}$ be the blowup of $\overline{\mathcal{M}}_{1,2}$ in x (Figure 2), with $\tilde{C}$ the pullback of C . The curve C_x has two irreducible components Y_1, Y_2 (say Y_1 carries p_1), and the pullbacks of these to $\tilde{C}$ are prime divisors supported over the exceptional locus of the blowup, which we denote by $\tilde{Y}_i$. We would like to say that LogDR satisfies the invariance

$$\text{LogDR}(\mathcal{L}) = \text{LogDR}(\mathcal{L}(\tilde{Y}_1)),$$

but this makes no sense because $\tilde{Y}_1$ is only a Weil divisor, not a Cartier divisor over the ‘danger’ points marked in Figure 2. To rectify this, we blow up $\tilde{C}$ quite carefully so that the result $\tilde{\tilde{C}}$ is still a prestable curve, but now $\tilde{Y}_1$ is a Cartier divisor on $\tilde{\tilde{C}}$. Then the invariance

$$\text{LogDR}(\mathcal{L}) = \text{LogDR}(\mathcal{L}(\tilde{Y}_1))$$

makes sense on $\tilde{\tilde{C}}$, and is moreover true.

It is at this point perhaps not clear what we have gained; we have replaced the rather simple bundle $\mathcal{L}$ on C with the rather complicated $\mathcal{L}(\tilde{Y}_1)$ on $\tilde{\tilde{C}}$. The magic is that $\mathcal{L}(\tilde{Y}_1)$ has multidegree $\underline{0}$ – that is, it has degree 0 on every irreducible component of every fibre of $\tilde{\tilde{C}}$ (with the exception of the danger points, which we will sweep under the carpet for now). Now, for

a line bundle of multidegree $\underline{0}$, the cycle LogDR is just the pullback of the corresponding DR (Lemma 4.8), and we know the latter to be tautological by Pixton’s formula [BHP⁺20].

1.6 Interpretation as a new invariance of LogDR

Dimitri Zvonkine asked us whether the six invariance properties listed in [BHP⁺20, § 0.6], together with knowledge of DR for families C/S and $\mathcal{L}$ of multidegree $\underline{0}$, would be enough to determine DR completely. The answer is no, essentially because the invariances in [BHP⁺20] do not allow us to twist by vertical divisors on C coming from non-separating edges. We saw above how to rectify this in the case of $\widetilde{\mathcal{M}}_{1,2}$; here we give a more general statement of the new invariance satisfied by LogDR .

Let C/S be a log curve with S log regular and $\mathcal{L}$ on C a line bundle. We say that C/S is *twistable*² if there exists a Cartier divisor D on C supported over the boundary of S (that is, the points of S where the log structure is non-trivial) and such that $\mathcal{L}(D)$ has multidegree $\underline{0}$. We write $\text{LogDR}(\mathcal{L})$ for the pullback of LogDR from $\mathfrak{Jac}$ along the map $S \rightarrow \mathfrak{Jac}$ induced by $\mathcal{L}$ and $\text{DR}(\mathcal{L}(D))$ for the pullback of DR from $\mathfrak{Jac}$ along the map $S \rightarrow \mathfrak{Jac}$ induced by $\mathcal{L}(D)$. Viewing $\text{DR}(\mathcal{L}(D))$ as an element of $\text{LogCH}(S)$ by pullback, our new invariance states

$$\text{LogDR}(\mathcal{L}) = \text{DR}(\mathcal{L}(D)). \quad (1.6.1)$$

That this invariance holds is quite straightforward once the definitions are set up correctly; see Lemma 4.8. However, there are not enough twistable families that LogDR is determined by DR and the invariance (1.6.1); requiring multidegree $\underline{0}$ over *every* point in S is too restrictive a condition (for example, it fails over the ‘danger’ points in $\widetilde{\mathcal{M}}_{1,2}$ mentioned above). Because of this, we introduce in Definition 4.11 a notion of *almost-twistable* families. In Lemma 4.14, we show the analogue of (1.6.1) for almost-twistable families, and in Lemma 4.18, we show that there are enough almost-twistable families to completely determine LogDR from DR.

1.7 Notation and conventions

We work with algebraic stacks in the sense of [Sta13] and with log structures in the sense of Fontaine–Illusie–Kato, for which we find [Ogu18] and [Kat89b] particularly useful general references. The sheaf of monoids on a log scheme (or stack) X is denoted by M_X , and the characteristic (or ghost) sheaf is denoted by $\bar{M}_X$, with groupifications M_X^{gp} and $\bar{M}_X^{\text{gp}}$. Occasionally, we write $\underline{X}$ for the underlying scheme (or algebraic stack) of X .

We work over a field or Dedekind scheme k equipped with trivial log structure. We work in the category of fine saturated (fs) log schemes (and stacks) over k . In Theorem 5.6 and Sections 4.6 and 4.7, we assume that k has characteristic 0, so that we can apply the results of [BHP⁺20]; it is plausible that the results would become false were this assumption omitted.

A *log algebraic stack* is an algebraic stack equipped with an (fs) log structure.

We work almost exclusively with operational Chow groups with rational coefficients, as defined in [BHP⁺20, § 2], denoted by CH.

²We thank Rahul Pandharipande for suggesting this terminology.

2. Logarithmic Chow rings

2.1 Logarithmic Chow rings of algebraic stacks

In this section, we make a slight generalisation of some of the ideas from [HPS19]; see also [MPS21]. We work extensively with log schemes (and stacks) which are both regular and log regular, equivalently, with log structures that are induced by normal crossings divisors (see [Niz06]). We make quite some effort in this and other sections to avoid unnecessary separatedness or quasi-compactness assumptions and to work with algebraic stacks in place of (for example) schemes. This is not (primarily?) due to a particular personal preference but rather because the objects we consider (such as the stack of log curves, or its universal Picard space) make this essential.

DEFINITION 2.1 ([ALT19, Example 4.3]). A morphism $f: X \rightarrow Y$ of log algebraic stacks is a *monoidal alteration* if it is proper, log étale, and is an isomorphism over the locus in Y where the log structure is trivial.

Examples of monoidal alterations are log blowups and root stacks. We expect that every monoidal alteration can be dominated by a composition of log blowups and root stacks but have not written down a proof.

DEFINITION 2.2. Let X be an algebraic stack locally of finite type over k . We define $\mathrm{CH}(X)$ to be the operational Chow group of X with rational coefficients, using finite-type algebraic spaces as test objects; see [BHP⁺20, § 2] for details.

Remark 2.3. If in addition X is smooth and Deligne–Mumford, then the intersection pairing induces an isomorphism from the usual Chow ring of X (as defined by Vistoli [Vis89]) to the operational Chow ring $\mathrm{CH}(X)$.

DEFINITION 2.4. Let X be a log smooth stack of finite type over k . We define the (operational) log Chow ring of X to be

$$\mathrm{LogCH}(X) = \mathrm{colim}_{\tilde{X}} \mathrm{CH}(\tilde{X}),$$

where the colimit runs over monoidal alterations $\tilde{X} \rightarrow X$ with $\tilde{X}$ smooth over k .

Remark 2.5. A fibre product of monoidal alterations is again a monoidal alteration; hence the above colimit is filtered. This implies that the colimit commutes with the forgetful functor to the category of sets. More concretely, the colimit can be realised as the disjoint union of the Chow rings of monoidal alterations of X , modulo setting two elements of different Chow rings to be equivalent if they become equal in some common refinement of their home monoidal alterations.

DEFINITION 2.6. Let $z \in \mathrm{LogCH}(X)$, and let $U \hookrightarrow X$ be a quasi-compact open. We say that the restriction of z to U is *determined* on a monoidal alteration $\tilde{U} \rightarrow U$ if there exists a cycle $z' \in \mathrm{CH}(\tilde{U})$ in the equivalence class of z as defined in the above remark; we then call z' the *determination* of z on $\tilde{U}$.

Remark 2.7. Because we work with rational coefficients, taking the colimit over log blowups would yield the same operational Chow ring; in particular, our log Chow ring is the same as that in [HPS19, § 9]. Throughout the paper, we use the possibility of determining a cycle on a (smooth) log blowup without further comment.

Remark 2.8. The idea of allowing monoidal alterations rather than just log blowups was suggested to the authors by Leo Herr. It will play little role in most of the paper but is absolutely essential in Section 4.6, where it allows us to apply ideas of [ALT19] on canonical resolution of singularities.

Remark 2.9. The ring $\operatorname{colim}_{\tilde{X}} \operatorname{CH}(\tilde{X})$ can be realised concretely as the disjoint union of the rings $\operatorname{CH}(\tilde{X})$, modulo the equivalence relation where we set cycles z_1 on $\tilde{X}_1$ and z_2 on $\tilde{X}_2$ to be equivalent if there exists a monoidal alteration $\tilde{X}$ dominating both $\tilde{X}_1$ and $\tilde{X}_2$ and on which the pullbacks of z_1 and z_2 coincide.

2.2 Operations on the logarithmic Chow ring

Throughout this subsection, X and Y are log smooth stacks of finite type over k .

DEFINITION 2.10 (LogCH is a CH-algebra). Viewing X as a trivial log blowup of itself induces a ring homomorphism $\operatorname{CH}(X) \rightarrow \operatorname{LogCH}(X)$.

DEFINITION 2.11 (Pullback for LogCH). Let $f: X \rightarrow Y$ be a morphism, and let $z \in \operatorname{LogCH}(Y)$. Let $\tilde{Y} \rightarrow Y$ be a log blowup on which z is determined. Then $X \times_Y \tilde{Y} \rightarrow X$ is a log blowup, and we write $\tilde{f}: X \times_Y \tilde{Y} \rightarrow \tilde{Y}$. We have a pullback $\tilde{f}^*z \in \operatorname{CH}(\tilde{X})$, which is independent of all choices, and the construction yields a ring homomorphism

$$f^*: \operatorname{LogCH}(Y) \rightarrow \operatorname{LogCH}(X).$$

LEMMA 2.12. Let $f: X \rightarrow Y$ be a morphism; then the following diagram commutes:

$$\begin{array}{ccc} \operatorname{CH}(Y) & \longrightarrow & \operatorname{LogCH}(Y) \\ \downarrow f^* & & \downarrow f^* \\ \operatorname{CH}(X) & \longrightarrow & \operatorname{LogCH}(X). \end{array}$$

DEFINITION 2.13 (Pushforward from LogCH to CH). Suppose that X is smooth, and let $z \in \operatorname{LogCH}(X)$. Let $\tilde{X} \rightarrow X$ be a log blowup on which z is determined, with $\tilde{X}$ smooth. Then $\pi: \tilde{X} \rightarrow X$ is proper and local complete intersection (lci), so we have a proper pushforward on operational Chow $\pi_*: \operatorname{CH}(\tilde{X}) \rightarrow \operatorname{CH}(X)$. These assemble into a pushforward

$$\operatorname{LogCH}(X) \rightarrow \operatorname{CH}(X).$$

2.3 Extension to the non-quasi-compact case

DEFINITION 2.14. Let X be a log smooth log algebraic stack over k (we no longer assume X to be quasi-compact). Let $\operatorname{qOp}(X)$ denote the category of open substacks of X which are quasi-compact. We define the (operational) log Chow ring of X to be

$$\operatorname{LogCH}(X) = \lim_{U \in \operatorname{qOp}(X)} \operatorname{LogCH}(U).$$

Remark 2.15. Morally, we can think of an element of $\operatorname{LogCH}(X)$ as an (operational) cycle on the valuativisation³ of X , which can be everywhere-locally represented on some finite log blowup of X . In the absence of a good theory of Chow groups of valuativisations of algebraic stacks, we make the above definition.

Remark 2.16. All of the constructions of Section 2.2 carry through to this setting by restricting to suitable quasi-compact opens. We will make use of these extensions without further comment.

³See for example [Kat89a].

3. Tautological subrings of logarithmic Chow rings

In this section, we develop a fairly general theory of piecewise-polynomial functions on log algebraic stacks, generalising the theory for toric varieties (for which see [Pay06] and the references therein). We use these piecewise-polynomial functions to build tautological subrings of the log Chow ring. Once again we need only log blowups in this section; root stacks are unnecessary.

In the toric case one can hope to realise every element of the Chow ring in terms of piecewise-polynomial functions, which is far from the case in the our context; for example, all piecewise-polynomial functions are zero on a scheme equipped with the trivial log structure, but the Chow ring can be large and interesting. However, in the presence of a non-trivial log structure, the piecewise-polynomial functions can still generate many interesting Chow elements.

The theory in this section was largely developed before we became aware of the related work of Molcho, Pandharipande, and Schmitt [MPS21], where ‘normally decorated strata classes’ approximately correspond to classes coming from our piecewise-polynomial functions. Their approach is probably better for writing formulae for (log) tautological classes, and ours has the advantage that piecewise polynomials on opens can be glued (which is very useful when working on large algebraic stacks as we do in this paper; as far as we are aware, the theory in [MPS21] has so far only been developed for finite-type Deligne–Mumford stacks).

3.1 Strict piecewise-polynomial functions

Let $(X, \mathcal{O}_X)$ be a ringed site and $\mathcal{M}$ a sheaf of $\mathcal{O}_X$ -modules. We write $\mathrm{Sym} \mathcal{M}$ for the sheafification of the presheaf $U \mapsto \mathrm{Sym}(\mathcal{M}(U))$; it is a sheaf of $\mathcal{O}_X$ -algebras. If X is any site and $\mathcal{A}$ a sheaf of abelian groups, then we view $\mathcal{A}$ as a sheaf of modules for the constant sheaf of rings $\mathbb{Z}$, yielding a sheaf $\mathrm{Sym} \mathcal{A}$ of graded $\mathbb{Z}$ -algebras.

Example 3.1. If X is a scheme and $\mathcal{A}$ is the constant sheaf $\mathbb{Z}^n$ of abelian groups, then $\mathrm{Sym} \mathcal{A}$ is the constant sheaf $\mathbb{Z}[x_1, \dots, x_n]$.

DEFINITION 3.2. We define the *sheaf of strict piecewise-polynomial functions* on a log algebraic stack S as

$$\mathrm{sPP}_S := \mathrm{Sym} \bar{\mathcal{M}}_S^{\mathrm{gp}}.$$

We write

$$\mathrm{sPP}_S^n = \mathrm{Sym}^n \bar{\mathcal{M}}_S^{\mathrm{gp}}$$

for the graded pieces, and *strict piecewise-linear* functions are

$$\mathrm{sPP}_S^1 = \mathrm{Sym}^1 \bar{\mathcal{M}}_S^{\mathrm{gp}} = \bar{\mathcal{M}}_S^{\mathrm{gp}}. \quad (3.1.1)$$

Remark 3.3. (i) If S is a toric variety, then strict piecewise-linear (or piecewise-polynomial) functions on S correspond exactly to piecewise-linear (or piecewise-polynomial) functions on the fan of S which are linear (or polynomial) on each cone. Later (Definition 3.15) we will generalise this to allow functions which are linear (or polynomial) on some subdivision of the fan.

(ii) The sheaf $\bar{\mathcal{M}}_S^{\mathrm{gp}}$ makes sense on the big strict étale site of S , so the same holds for the sheaf sPP_S .

(iii) There is natural map $\mathrm{Sym}^n (\bar{\mathcal{M}}_S^{\mathrm{gp}}(S)) \rightarrow \mathrm{sPP}_S^n(S)$, but it is in general not surjective unless $n = 1$; see Example 3.4. This will play a prominent role in what follows.

(iv) Given a map of log algebraic stacks $f: S' \rightarrow S$, there is a natural map $f^* \bar{\mathcal{M}}_S \rightarrow \bar{\mathcal{M}}_{S'}$, inducing a natural map of sheaves of $\mathbb{Z}$ -algebras $f^* \mathrm{sPP}_S \rightarrow \mathrm{sPP}_{S'}$.

Example 3.4. Let $\underline{S} = \mathbb{P}_k^2$, and let E be an irreducible nodal cubic in $\underline{S}$, with complement $i: U \hookrightarrow \underline{S}$. We define $M_S = i_*\mathcal{O}_U$, so that $\bar{M}_S(S) = \mathbb{N}$ and $\text{Sym}(\bar{M}_S^{\text{gp}}(S)) = \mathbb{Z}[e]$, where e corresponds to the divisor E . There is an étale chart for S at the singular point of E given by $k[[a, b]]$, where a, b correspond to the two branches of E through the singular point. The image of $\text{Sym}^2(\bar{M}_S^{\text{gp}}(S))$ is the free module $\mathbb{Z}\langle(a+b)^2\rangle$. However, there is another global section of sPP_S^2 given by ab , and in fact $\text{sPP}_S^2(S) = \mathbb{Z}\langle(a+b)^2, ab\rangle = \mathbb{Z}\langle a^2 + b^2, ab\rangle$.

3.2 Simple log algebraic stacks

3.2.1 Barycentric subdivision. If S is a regular log regular log algebraic stack, then by [Niz06, §5.2], there exists a unique normal crossings divisor Z on S (the *boundary divisor* of S) with complement $i: U \rightarrow S$ and $M_S = i_*\mathcal{O}_U$. We write the irreducible components of Z as $(D_i)_{i \in I}$.

If S is a regular log regular atomic⁴ log scheme, then we define the *barycentric ideal sheaf* to be the product

$$\prod_{\emptyset \neq J \subseteq I} \mathcal{I}\left(\bigcap_{j \in J} D_j\right)$$

over *non-empty* subsets $J \subseteq I$ and the *barycentric subdivision* of S to be the blowup of S along the barycentric ideal sheaf. This blowup is stable under strict smooth pullback, defining a barycentric subdivision of any log regular log algebraic stack. A more explicit description can be found in [MPS21, §5.3].

3.2.2 Simple log algebraic stacks.

DEFINITION 3.5. If S is a regular log regular log algebraic stack with boundary divisor⁵ $Z = \bigcup_{i \in I} D_i$, we say that S is *simple* if for every $J \subseteq I$, the fibre product

$$D_J := \bigtimes_{j \in J, S} D_j \tag{3.2.1}$$

is regular and the natural map on sets of connected components $\pi_0(D_J) \rightarrow \pi_0(S)$ is injective. The closed connected substacks D_J are the *closed strata* of S .

This condition is more restrictive than requiring the boundary divisor to be a strict normal crossings divisor. Consider the union of a line and a smooth conic in $\mathbb{P}^2$ meeting at two points; then the intersection is not connected.

3.2.3 Simplifying blowups.

LEMMA 3.6. *Let S be a log regular log algebraic stack. Then there exists a log blowup $\tilde{S} \rightarrow S$ such that $\tilde{S}$ is simple.*

The proof consists of three observations:

- (i) By [IT14] there exists a *functorial* resolution algorithm for log regular log schemes; hence there exists a log blowup of S which is regular and log regular.
- (ii) If S is regular log regular, then the barycentric subdivision has strict normal crossings boundary (that is, the substacks D_J of (3.2.1) are regular).

⁴In the sense of [AW18]: S has a unique stratum that is closed and connected, and the restriction of the characteristic monoid to this stratum is a constant sheaf.

⁵Here we implicitly mean that the D_i are reduced and irreducible substacks of pure codimension 1.

- (iii) If S is regular log regular with strict normal crossings boundary, then the barycentric subdivision is simple.

3.2.4 Piecewise polynomials as polynomials in boundary divisors. For an algebraic stack X , we write $\text{Div}(X)$ for the monoid of isomorphism classes of pairs $(\mathcal{L}, \ell)$, where $\mathcal{L}$ is a line bundle on X and $\ell \in \mathcal{L}(X)$ a section, with monoid operation given by tensor product.

Let S be a log algebraic stack and $m \in \bar{M}_S(S)$. The preimage $\mathcal{O}_S(-m)^\times$ of m in M_S is an $\mathcal{O}_S^\times$ -torsor, and the log structure equips it with a map to $\mathcal{O}_S(-m)^\times \rightarrow \mathcal{O}_S$. This map admits a unique $\mathcal{O}_S^\times$ -equivariant extension to a map of line bundles $\mathcal{O}_S(-m) \rightarrow \mathcal{O}_S$, where we built $\mathcal{O}_S(-m)$ from $\mathcal{O}_S(-m)^\times$ by filling in the zero section. Dualising gives a map $\mathcal{O}_S \rightarrow \mathcal{O}_S(m) := \mathcal{O}_S(-m)^\vee$, and the image of the section 1 of $\mathcal{O}_S$ gives a section of $\mathcal{O}_S(m)$. This defines a map

$$\mathcal{O}_S(-): \bar{M}_S(S) \rightarrow \text{Div}(S). \quad (3.2.2)$$

This can be upgraded to a monoidal functor of fibred symmetric monoidal categories; see [BV12, §3.1].

If the log structure on S is trivial over a schematically dense open $U \subseteq S$ (for example, this holds if S is log regular), then the given section of $\mathcal{O}_S(m)$ is non-vanishing over U and so defines an effective Cartier divisor on S supported away from U , which we denote by $\text{div } \mathcal{O}_S(m)$.

Now suppose that S is a quasi-compact regular log regular log algebraic stack with boundary divisor $Z = \bigcup_{i \in I} D_i$ (with each D_i irreducible), and write $\langle D_i : i \in I \rangle$ for the free commutative monoid generated by the D_i (so $\langle D_i : i \in I \rangle^{\text{gp}}$ is the group of divisors on S with support contained in Z). Then the effective divisors $\text{div } \mathcal{O}_S(m)$ are supported on Z , hence naturally lie in $\langle D_i : i \in I \rangle$. Using that the rank of $\bar{M}_{S,s}$ is equal to the number of analytic branches of the D_i passing through s , one easily deduces the following.

LEMMA 3.7. *Sending m to $\text{div } \mathcal{O}_S(m)$ gives an isomorphism of monoids*

$$\bar{M}_S(S) \rightarrow \langle D_i : i \in I \rangle. \quad (3.2.3)$$

Now suppose in addition that the D_i form a divisor with *strict* normal crossings (that is, that all the fibre products in (3.2.1) are regular). Given $s \in S$, let $I_s = \{i \in I : s \in D_i\}$, so that $\{D_i : i \in I_s\}$ is the set of branches of Z through s . Then (for example by applying the above discussion to a small Zariski neighbourhood of s) we obtain an isomorphism

$$\bar{M}_{S,s} \xrightarrow{\sim} \langle D_i : i \in I_s \rangle. \quad (3.2.4)$$

The restriction map simply corresponds to the map $\langle D_i : i \in I \rangle \rightarrow \langle D_i : i \in I_s \rangle$ sending those D_i with $i \notin I_s$ to zero; more precisely, the square

$$\begin{array}{ccc} \bar{M}_S(S) & \xrightarrow{=} & \langle D_i : i \in I \rangle \\ \downarrow \text{res} & & \downarrow \\ \bar{M}_{S,s} & \xrightarrow{=} & \langle D_i : i \in I_s \rangle \end{array}$$

commutes.

The isomorphism (3.2.3) and the definition of the symmetric algebra yield an isomorphism

$$\text{Sym}(\bar{M}_S(S)^{\text{gp}}) \xrightarrow{\sim} \mathbb{Z}[D_i : i \in I]$$

to the free commutative ring on the D_i . Similarly, one obtains an isomorphism

$$\text{sPP}_{S,s} = \text{Sym}(\bar{M}_{S,s}^{\text{gp}}) \xrightarrow{\sim} \mathbb{Z}[D_i : i \in I_s].$$

We obtain a corresponding commutative diagram

$$\begin{array}{ccc}
 \mathrm{Sym}(\bar{M}_S(S)^{\mathrm{gp}}) & \xrightarrow{=} & \mathbb{Z}[D_i : i \in I] \\
 \downarrow \mathrm{res} & & \downarrow \\
 \mathrm{Sym}(\bar{M}_{S,s}^{\mathrm{gp}}) & \xrightarrow{=} & \mathbb{Z}[D_i : i \in I_s],
 \end{array} \tag{3.2.5}$$

where again the right vertical map sends any D_i with $i \notin I_s$ to zero.

3.2.5 Global generation on simple log schemes. In this section, we prove the key technical result on piecewise-polynomial functions on log stacks.

THEOREM 3.8. *Let S be a quasi-compact simple log algebraic stack. Then the natural map of $\mathbb{Z}$ -algebras*

$$\mathrm{Sym}(\bar{M}_S^{\mathrm{gp}}(S)) \rightarrow (\mathrm{Sym} \bar{M}_S^{\mathrm{gp}})(S)$$

is surjective.

In other words, $\mathrm{PP}_S(S)$ is a quotient of the symmetric algebra on $\bar{M}_S(S)$; every global piecewise-polynomial function can be written *globally* as a polynomial in piecewise-linear functions. We thank the referee for suggesting the following proof, which is much simpler than the one we started with.

Proof. Given $\underline{n} \in \mathbb{N}^I$, we write $D^{\underline{n}} \in \mathbb{Z}[D_i : i \in I]$ for the corresponding monomial in the D_i and $Z(D^{\underline{n}})$ for the fibre product over S of those D_i with $\underline{n}_i \neq 0$; this only depends on whether each $\underline{n}_i$ is 0 and is always either empty or irreducible (by our simplicity assumption).

Now let $f \in (\mathrm{Sym} \bar{M}_S^{\mathrm{gp}})(S)$; we construct explicitly a preimage in $\mathrm{Sym}(\bar{M}_S^{\mathrm{gp}}(S))$ by giving a coefficient for each monomial $D^{\underline{n}}$.

First suppose that $Z(D^{\underline{n}})$ is empty; then $D^{\underline{n}}$ maps to zero in $\mathrm{Sym}(\bar{M}_{S,s}^{\mathrm{gp}})$ for every $s \in S$, hence maps to zero in $\mathrm{Sym}(\bar{M}_S^{\mathrm{gp}})$ by the sheaf property. We set $f_{\underline{n}} = 0$ for each such $\underline{n}$.

Now take an $\underline{n} \in \mathbb{Z}^I$ such that $Z(D^{\underline{n}})$ is non-empty, and let η be its generic point. Then $D^{\underline{n}}$ maps to a non-zero element of $\mathbb{Z}[D_i : i \in I_\eta] = \mathrm{Sym}(\bar{M}_{S,\eta}^{\mathrm{gp}})$, and we write $f_{\underline{n}}$ for the coefficient of $D^{\underline{n}}$ in the restriction of f to $\mathrm{Sym}(\bar{M}_{S,\eta}^{\mathrm{gp}})$.

It is easy to check that only finitely many $f_{\underline{n}}$ can be non-zero. We define

$$F = \sum_{\underline{n} \in \mathbb{N}^I} f_{\underline{n}} D^{\underline{n}} \in \mathbb{Z}[D_i : i \in I] = \mathrm{Sym}(\bar{M}_S^{\mathrm{gp}}(S)).$$

It is easy to see that the image of F equals f because this can be checked one stratum at a time, and each stratum appears as some intersection of D_i . $\square$

3.3 Map to the Chow group

3.3.1 Map on divisors. Composing the map $\bar{M}_S(S) \rightarrow \mathrm{Div}(S)$ of (3.2.2) with the (operational) first Chern class yields a group homomorphism

$$\Phi^1 : \bar{M}_S^{\mathrm{gp}}(S) \rightarrow \mathrm{CH}^1(S), \tag{3.3.1}$$

with image contained in the subgroup generated by Cartier divisors.

3.3.2 *The case of simple finite-type stacks.* Let S be a simple log algebraic stack, smooth⁶ over k . The operational Chow group $\mathrm{CH}(S)$ has a commutative ring structure coming from composition of operations. As such, the map

$$\Phi^1: \bar{M}_S(S) \rightarrow \mathrm{CH}^1(S)$$

of (3.3.1) extends uniquely to a ring homomorphism

$$\Phi': \mathrm{Sym}(\bar{M}_S(S)) \rightarrow \mathrm{CH}(S).$$

LEMMA 3.9. *Any element of the kernel of the surjection $\mathrm{Sym}^n(\bar{M}_S^{\mathrm{gp}}(S)) \rightarrow (\mathrm{Sym}^n \bar{M}_S^{\mathrm{gp}})(S)$ maps to zero in $\mathrm{CH}(S)$.*

Proof. Let P be a polynomial in boundary divisors on S which maps to zero in $(\mathrm{Sym}^n \bar{M}_S^{\mathrm{gp}})(S)$, and let $s \in S$ be a point; then P maps to zero in $\mathrm{Sym}^n \bar{M}_{S,s}$. Write $D_1, \dots, D_n$ for the irreducible components of the boundary divisor of S , with $s \in D_i$ if and only if $i \leq r$ for some $1 \leq r \leq n$. Then (3.2.5) becomes the commutative diagram of rings

$$\begin{array}{ccc} \mathrm{Sym}^n(\bar{M}_S^{\mathrm{gp}}(S)) & \xrightarrow{=} & \mathbb{Z}[D_1, \dots, D_n] \\ \downarrow & & \downarrow \\ \mathrm{Sym}^n \bar{M}_{S,s}^{\mathrm{gp}} & \xrightarrow{=} & \mathbb{Z}[D_1, \dots, D_r], \end{array}$$

where the right vertical arrow sends D_i to 0 for $r < i \leq n$. In particular, we see that every monomial in the D_i with non-zero coefficient in P must contain some D_i for $r < i \leq n$ with non-zero exponent. This implies that the corresponding set-theoretic intersection of D_i does not contain s .

Since this argument holds for every $s \in S$, we see that each monomial in P has the set-theoretic intersection of its divisors being empty; hence it maps to zero in $\mathrm{CH}(S)$. $\square$

Hence this map Φ' descends to a unique ring homomorphism

$$\Phi: (\mathrm{Sym} \bar{M}_S)(S) = \mathrm{PP}_S(S) \rightarrow \mathrm{CH}(S),$$

whose degree 1 part is Φ^1 .

3.3.3 *The case of log smooth finite-type stacks.* Let S be a quasi-compact log smooth log algebraic stack over k . By Lemma 3.6, there exists a log blowup $\pi: \tilde{S} \rightarrow S$ with $\tilde{S}$ simple. We define

$$\Phi_S: (\mathrm{Sym} \bar{M}_S)(S) = \mathrm{sPP}_S(S) \rightarrow \mathrm{CH}(S)$$

as the composite

$$(\mathrm{Sym} \bar{M}_S)(S) \rightarrow \mathrm{Sym} \bar{M}_{\tilde{S}}(\tilde{S}) \xrightarrow{\Phi_{\tilde{S}}} \mathrm{CH}(\tilde{S}) \xrightarrow{\pi_*} \mathrm{CH}(S).$$

Lemma 3.6 actually yields a *canonical* choice of log blowup π , but we should still check that the map Φ_S is independent of the choice of π (for example, if S was already simple, we do not want to have changed the map by blowing up).

⁶If k is a field of characteristic 0, then here being smooth is equivalent to being locally of finite type (since simple implies regular).

LEMMA 3.10. *Let $\pi: \tilde{S} \rightarrow S$ be a log blowup with S and $\tilde{S}$ simple. The diagram*

$$\begin{array}{ccc} \mathrm{sPP}_{\tilde{S}}(\tilde{S}) & \xrightarrow{\Phi_{\tilde{S}}} & \mathrm{CH}(\tilde{S}) \\ \pi^* \uparrow & & \downarrow \pi_* \\ \mathrm{sPP}_S(S) & \xrightarrow{\Phi_S} & \mathrm{CH}(S) \end{array}$$

commutes.

Proof. Since S is simple, it is enough to check this for a monomial in elements of $\bar{M}_S(S)$ corresponding to prime boundary divisors on S , say $\prod_{a \in A} D_a$. Applying π^* corresponds to taking the total transforms of these divisors up to $\tilde{S}$. We then need to show that

$$\pi_* \left(\prod_a \pi^* D_a \right) = \prod_a D_a,$$

which follows from the projection formula and the fact that $\pi_* \pi^*$ is the identity. $\square$

LEMMA 3.11. *For any log regular S , the map Φ_S is independent of the choice of log blowup $\pi: \tilde{S} \rightarrow S$.*

Proof. Reduce to one blowup dominating another; then apply Lemma 3.10. $\square$

Example 3.12. We resume Example 3.4 and recall that $\mathrm{sPP}^2(S) = \mathbb{Z} \langle (a+b)^2, ab \rangle$. Then $(a+b)^2$ maps to $E^2 \in \mathrm{CH}^2(S)$, and ab maps to the class of the singular point of E in $\mathrm{CH}^2(S)$.

Remark 3.13. If S is simple, then we can choose π to be the identity, and it is clear that $\Phi_S: \mathrm{sPP}_S(S) \rightarrow \mathrm{CH}(S)$ is a ring homomorphism. If S is not simple, then we suspect that Φ_S is still a ring homomorphism, but we have not managed to prove it.

3.3.4 *The case of log regular stacks locally of finite type.* Let $\underline{S}$ be an algebraic stack locally of finite type over k , and write $\mathrm{qOp}(\underline{S})$ for the category of open substacks of $\underline{S}$ which are quasi-compact over k , with maps over $\underline{S}$. Then one sees easily that

$$\mathrm{CH}(\underline{S}) = \lim_{U \in \mathrm{qOp}(\underline{S})} \mathrm{CH}(U).$$

LEMMA 3.14. *Let $i: S_1 \hookrightarrow S_2$ be a strict open immersion of quasi-compact log smooth log algebraic stacks over k . The diagram*

$$\begin{array}{ccc} \mathrm{sPP}_{S_2}(S_2) & \xrightarrow{\Phi_2} & \mathrm{CH}(S_2) \\ \downarrow i^* & & \downarrow i^* \\ \mathrm{sPP}_{S_1}(S_1) & \xrightarrow{\Phi_1} & \mathrm{CH}(S_1) \end{array}$$

commutes.

Proof. A simplifying blowup for S_2 pulls back to one for S_1 , so we may assume both S_i simple. Then it is enough to check the result for divisors, since both maps i^* are ring homomorphisms, as are Φ_1 and Φ_2 (by our simplicity assumption), and $\mathrm{P}_{S_2}(S_2)$ is generated in degree 1. But the result for divisors is easy. $\square$

Now let S be a log smooth log algebraic stack over k . Given $p \in \mathrm{PP}_S(S)$ and any quasi-compact $U \hookrightarrow S$, we restrict p to $p_U \in \mathrm{sPP}_U(U)$, yielding an element $\Phi_U(p_U) \in \mathrm{CH}(U)$. By Lemma 3.14, these glue, yielding a map

$$\Phi_S: \mathrm{sPP}_S(S) \rightarrow \mathrm{CH}(S). \quad (3.3.2)$$

3.4 General piecewise polynomials and the log-tautological ring

DEFINITION 3.15. For a log algebraic stack S , we define the group of *piecewise-polynomial functions* as

$$\mathrm{PP}'(S) = \operatorname{colim}_{\tilde{S} \rightarrow S} \mathrm{sPP}(\tilde{S}),$$

where $\tilde{S} \rightarrow S$ runs over all log blowups of S .

LEMMA 3.16. *The pullback $\mathrm{sPP}(S) \rightarrow \mathrm{sPP}(\tilde{S})$ is injective for $\tilde{S} \rightarrow S$ any log blowup, so the natural maps to the colimit are injective.*

Proof. It suffices to show this locally, so we reduce to the atomic case. It is then enough to check that the natural map $\bar{\mathbf{M}}_S(S) \rightarrow \bar{\mathbf{M}}_{\tilde{S}}(\tilde{S})$ is injective. This is clear from the construction of the blowup in the toric case, but any log blowup is locally a strict base-change of a toric blowup. $\square$

We define the sheaf of piecewise polynomials PP on the small strict étale site of S as the sheafification of the presheaf of rings $\mathrm{PP}': U \mapsto \mathrm{PP}'(U)$. This sheaf property then immediately yields

$$\mathrm{PP}(S) = \lim_{U \in \mathrm{qOp}(S)} \mathrm{PP}(U).$$

The natural maps

$$\Phi_i^{\log}: \mathrm{PP}(U_i) \rightarrow \operatorname{colim}_{\tilde{U}_i} \mathrm{CH}(\tilde{U}_i)$$

then assemble into a ring homomorphism

$$\Phi^{\log}: \mathrm{PP}(S) \rightarrow \mathrm{LogCH}(S). \quad (3.4.1)$$

REMARK 3.17. The presheaf PP' is always separated and is a sheaf if S is quasi-compact and quasi-separated; we make the above construction to avoid having to worry about finding common refinements of blowups of very large stacks.

3.4.1 The log-tautological ring.

DEFINITION 3.18. Let S be a smooth log smooth log algebraic stack over k , and let $T \subseteq \mathrm{CH}(S)$ be a subring. We define $T^{\log} \subseteq \mathrm{LogCH}(S)$ to be the sub- T -algebra of $\mathrm{LogCH}(S)$ generated by the image of

$$\Phi^{\log}: \mathrm{PP}(S) \rightarrow \mathrm{LogCH}(S).$$

A natural application is to take $S = \overline{\mathcal{M}}_{g,n}$ and T to be the usual tautological subring of the Chow ring. We want to ensure that after carrying out our logarithmic constructions and pushing back down to $\overline{\mathcal{M}}_{g,n}$, we still have tautological classes.

DEFINITION 3.19. We say that a subring $T \subseteq \mathrm{CH}(S)$ is *tectonic*⁷ if the pushforward of $T^{\log}$ from $\mathrm{LogCH}(S)$ to $\mathrm{CH}(S)$ is equal to T .

Giving criteria for when a subring $T \subseteq \mathrm{CH}(S)$ is tectonic is somewhat subtle. Certainly if a subring is tectonic, then it must contain all boundary strata, and the converse holds if S is simple but not in general. Fortunately for us, a precise criterion has been worked out in [MPS21] for the

⁷It contains many strata, which are formed by overlaps of other strata, perhaps after some things blow up...

case where S is Deligne–Mumford and quasi-compact, which will be enough for our applications.⁸ Their criterion goes by way of defining certain *normally decorated strata classes* in $\mathrm{CH}(S)$; the definition is somewhat lengthy, and the details will not be so important for us. We need only the following lemma and the fact that the usual tautological ring of $\overline{\mathcal{M}}_{g,n}$ contains these normally decorated strata classes.

LEMMA 3.20. *Suppose that S is Deligne–Mumford and quasi-compact. Then a subring $T \subseteq \mathrm{CH}(S)$ is tectonic if and only if it contains all normally decorated strata classes.*

Proof. Let $\nu: \tilde{S} \rightarrow S$ be a log blowup. We denote by $R^*(S)$ the ring of normally decorated strata classes on S , and similarly for $\tilde{S}$. By definition, $R^*(\tilde{S})$ contains⁹ all boundary strata of $\tilde{S}$, and $\nu_*(R^*(\tilde{S})) \subseteq R^*(S)$ by [MPS21, Theorem 13]. This implies that every T containing $R^*(S)$ is tectonic (which is the direction we will use). We deduce the converse from [MPS21, Theorem 11] and the fact that (on a simple log blowup) $T^{\log}$ contains all boundary divisors. $\square$

3.5 Constructing a class

In this subsection, we present a construction, formulated in a general setting, that will be used in Section 4.2 to define logarithmic double ramification cycles.

Suppose given the following data:

- (i) S/k , a quasi-separated log smooth log algebraic stack which is stratified by global quotients;¹⁰
- (ii) $f: X \rightarrow S$, a birational representable log étale morphism;
- (iii) J/k , an algebraic stack, and $i: e \hookrightarrow J$, a regularly embedded closed substack (or more generally an lci morphism);
- (iv) $\sigma: X \rightarrow J$, a morphism over k .

Also suppose that the base-change $X \times_J e$ is proper over S . Then we construct a class $[\sigma^*e]_{f,\log} \in \mathrm{LogCH}(S)$ – we often omit the f from the notation when it is clear from context.

The simplest case of our construction is when X is smooth and $f: X \rightarrow S$ is a log blowup (then $X \times_J e \rightarrow S$ is automatically proper). Then $\sigma^!e$ is a well-defined class on X and automatically gives an element of $\mathrm{LogCH}(S)$, which we denote by $[\sigma^*e]_{f,\log}$.

In the general case, a little more care is needed. Because $\mathrm{LogCH}(S)$ is defined as a limit over quasi-compact opens, we may assume that S is quasi-compact. Then by Lemma 3.25, there exist log blowups $\tilde{S} \rightarrow S$ and $\tilde{X} \rightarrow X$ and a strict open immersion $\tilde{f}: \tilde{X} \hookrightarrow \tilde{S}$ over f ; after further log blowup, we may also assume $\tilde{S}$ (and hence $\tilde{X}$) to be smooth.

DEFINITION 3.21. We call such an $\tilde{S} \rightarrow S$ a *sufficiently fine* log blowup (for $f: X \rightarrow S$) and $\tilde{X} \hookrightarrow \tilde{S}$ the *lift* of X .

⁸It seems likely that their results (perhaps with slight modification) will also hold in the setting of smooth log smooth algebraic stacks, but we have not verified the details.

⁹If we take $\tilde{S}$ simple, then $R^*(\tilde{S})$ is in fact generated by strata, but this is not needed for our argument.

¹⁰In practise, this last condition means that we must exclude $\mathfrak{M}_{1,0}$ from our results; but this is fairly harmless since we can just consider the corresponding cycle on $\mathfrak{M}_{1,1}$ with zero weighting on the new marking.

Set $Z = \tilde{X} \times_{\sigma, J, i} e$, and consider the diagram

$$\begin{array}{ccc} Z & \longrightarrow & e \\ \downarrow & & \downarrow i \\ j \swarrow \tilde{X} & \xrightarrow{\sigma} & J \\ \downarrow \tilde{f} & & \\ \tilde{S} & & \end{array}$$

We then define

$$[\sigma^* e]_{f, \log} = j_* i^! [\tilde{X}].$$

To unravel this formula, recall that i is lci, so we have a gysin morphism $i^!: A^*(\tilde{X}) \rightarrow A^*Z$. The composite $j: Z \rightarrow \tilde{S}$ is a closed immersion, in particular projective, so we have a pushforward $j_*: A^*Z \rightarrow A^*\tilde{S}$. Finally, $\tilde{S}$ is smooth, so the intersection product furnishes a map $A^*(S) \rightarrow \text{CH}(\tilde{S})$, and we have a natural inclusion $\text{CH}(\tilde{S}) \hookrightarrow \text{LogCH}(S)$.

Remark 3.22. In place of the above construction, it might be tempting to take the operational class on J defined by the regular embedding i , then pull it back to $\tilde{X}$. However, $\tilde{f}: \tilde{X} \rightarrow \tilde{S}$ is not necessarily proper, so we cannot push the result forward to define a class on $\tilde{S}$. The essential feature of our construction is that we only assume that j is proper, not $\tilde{f}$.

To see that the above construction is independent of the choice of $\tilde{S}$, we use that gysin pullbacks along lci maps commute with each other and with projective pushforward [Kre99, Theorem 2.1.12(xi)].

Remark 3.23. Let $\tilde{S} \rightarrow S$ be a sufficiently fine log blowup. Then $[\sigma^* e]_{f, \log}$ is determined on $\tilde{S}$ (in the sense of Definition 2.6).

LEMMA 3.24. *Let $\varphi: X' \rightarrow X$ be another birational representable log étale morphism, and write $f': X' \rightarrow S$, $\sigma': X' \rightarrow J$ for the obvious composites. Then*

$$[\sigma^* e]_{f, \log} = [\sigma'^* e]_{f', \log} \in \text{LogCH}(S).$$

Proof. Let $T \rightarrow S$ be a blowup that is sufficiently fine for $X' \rightarrow S$ and which dominates a sufficiently fine blowup for $X \rightarrow S$. Unravelling the definitions, one sees that the classes agree already in $\text{CH}(T)$. $\square$

The key to the above construction is the following lemma, whose proof is essentially the same as that of Lemma 6.1 of [Hol21].

LEMMA 3.25. *Let S be a regular log regular quasi-compact quasi-separated (qcqs) stack and $f: X \rightarrow S$ birational separated log étale representable. Then there exist log blowups $\tilde{S} \rightarrow S$ and $\tilde{X} \rightarrow X$ and a strict open immersion $\tilde{X} \rightarrow \tilde{S}$ over S .*

Probably this lemma is false if one drops either the quasi-compactness or quasi-separatedness assumptions, but we have not managed to write down an example and would be interested to see one.

Proof. First consider the case where S is an affine toric variety, given by some cone $c \simeq \mathbb{N}^r$. Then X is given by a fan F consisting of a collection of cones contained in c . Let $\bar{F}$ be a complete fan in c such that every cone in F is a union of cones in $\bar{F}$; after further refinement of $\bar{F}$, we can

assume that it corresponds to a log blowup $\tilde{S} \rightarrow S$. The restriction of $\tilde{F}$ to F gives a log blowup $\tilde{X} \rightarrow X$ and a strict open immersion $\tilde{X} \rightarrow \tilde{S}$.

In the case where S is an atomic log scheme, we can follow essentially the same procedure, where the cone $c \xrightarrow{\sim} \mathbb{N}^r$ is replaced by the stalk of the ghost sheaf over the closed stratum of S .

In the general case, we can find a smooth cover S by finitely many atomic patches (by quasi-compactness), and each intersection can be covered by finitely many atomic patches (by quasi-separatedness). A strict map of atomic patches just corresponds to some inclusion of a cone as a face of another cone: $\mathbb{N}^r \hookrightarrow \mathbb{N}^s$.

Given a face inclusion $\mathbb{N}^r \hookrightarrow \mathbb{N}^s$ and a subdivision of $\mathbb{N}^s$, we can pull the subdivision back to a (unique) subdivision of $\mathbb{N}^r$. But also, given a subdivision of $\mathbb{N}^r$, we can turn it into a subdivision of $\mathbb{N}^s$ in a *canonical* way, by taking the product. Hence if $\mathbb{N}^r \hookrightarrow \mathbb{N}^s$ is a face map (where we allow $r = s$) and we have subdivisions of $\mathbb{N}^r$ and $\mathbb{N}^s$, then we can find ‘common refinements’ to subdivisions of $\mathbb{N}^r$ and $\mathbb{N}^s$ which agree along the face map. Moreover, if both starting subdivisions were log blowups, then so are these common refinements.

To conclude the proof, we just need to extend this ‘common refinement’ procedure from a single face map to any diagram D of face maps with finitely many objects. Such a diagram necessarily also has finitely many morphisms (since there are only finitely many face maps between any two cones); hence the same is true for the category D' obtained by formally inverting all the maps in D . By the discussion in the previous paragraph, we can pull back a log blowup along any map in D' .

We are given a log blowup of each cone in D . For a fixed cone c , there are only finitely many pairs d, f , where d is another cone and $f: d \rightarrow c$ is a morphism in D' . We then give c the log blowup which is the superposition over all these pairs (f, d) of the pullback along f of the given log blowup of d . In this way we equip every object of D with a log blowup, in such a way that these are compatible along all the face maps in D . These then glue to a global log blowup of S , which pulls back to a global log blowup of X . $\square$

4. Logarithmic double ramification cycles

4.1 Notation

Here we introduce notation needed for applying the machinery developed in the previous two sections to moduli of curves and to double ramification cycles.

- (i) $\mathfrak{M}_{g,n}$ denotes the (smooth, algebraic) stack of prestable curves of genus g with n ordered disjoint smooth markings. This has a normal crossings boundary, inducing a log smooth log structure. Equivalently, this is the stack of log curves of genus g and n markings, with a choice of total ordering on the markings (see [Kat00], [GS13, Appendix A]; the underlying algebraic stack is then given by the machinery of minimal log structures [Gil12]).
- (ii) $\overline{\mathcal{M}}_{g,n}$ is the open substack of $\mathfrak{M}_{g,n}$ consisting of Deligne–Mumford–Knudsen stable curves.
- (iii) $\mathfrak{M} = \bigsqcup_{g,n} \mathfrak{M}_{g,n}$ denotes the stack of all log curves with a choice of total ordering on their markings. Often the genus and markings will not be so important to us, so we can use this more compact notation.
- (iv) C is the universal curve over $\mathfrak{M}$. We will abusively use the same notation for the tautological curve over any stack over $\mathfrak{M}$ (so, for example, for the universal curve over $\overline{\mathcal{M}}_{g,n}$).
- (v) $\mathfrak{Pic}$ is the relative Picard stack of C over $\mathfrak{M}$; objects are pairs of a curve and a line bundle

on the curve. This is smooth over $\mathfrak{M}$ with relative inertia $\mathbb{G}_m$; we equip it with the strict (pullback) log structure over $\mathfrak{M}$.

- (vi) $\mathfrak{Jac}$ denotes the connected component of $\mathfrak{Pic}$ corresponding to line bundles of (total) degree 0 on every fibre.
- (vii) J is the relative coarse moduli space over $\mathfrak{M}$ of the *fibrewise* connected component of identity in $\mathfrak{Jac}$ (or equivalently in $\mathfrak{Pic}$). Over the locus of smooth curves in $\mathfrak{M}$, this is an abelian variety, the classical jacobian. In general it is a semiabelian variety over $\mathfrak{M}$ which parametrises isomorphism classes of line bundles on $\mathcal{C}/\mathfrak{M}$ which have degree 0 on every irreducible component of every geometric fibre (sometimes we refer to this condition as having *multidegree* $\underline{0}$). The morphism $J \rightarrow \mathfrak{M}$ is separated, quasi-compact, and relatively representable by algebraic spaces (none of which hold for $\mathfrak{Pic}$ or $\mathfrak{Jac}$).
- (viii) $\bar{J}$ is the relative coarse moduli space of $\mathfrak{Jac}$ over $\mathfrak{M}$; it can be defined analogously to J except that we require total degree 0 instead of multidegree $\underline{0}$. In particular, we have an open immersion $J \hookrightarrow \bar{J}$, which is an isomorphism over the locus of irreducible curves.

LEMMA 4.1. *The stack $\mathfrak{Jac}$ is quasi-separated.*

Proof. First we check that $\mathfrak{M}$ is quasi-separated, equivalently, that the diagonal is qcqs. In other words, if C/S is a prestable curve, then $\text{Isom}_S(C)$ is qcqs over S – but this is well known.

Now we show that $\mathfrak{Jac}$ is quasi-separated over $\mathfrak{M}$. In other words, we fix a prestable curve C/S and a line bundle $\mathcal{L}$ on C and look at the automorphisms of $\mathcal{L}$ over C ; but this is just $\mathbb{G}_m$. $\square$

4.1.1 *Piecewise-linear functions.* If C/S is a log curve and $\alpha \in \bar{M}_C^{\text{gp}}(C)$, the *outgoing slope* at a marked section c of C/S is the image of α in the stalk of the relative characteristic monoid $\bar{M}_{C/S,s} = \mathbb{N}$.

DEFINITION 4.2. A strict piecewise-linear (sPL) function on a log curve C/S is an element $\alpha \in \bar{M}_C^{\text{gp}}(C)$ (cf. (3.1.1)) with all outgoing slopes vanishing.¹¹

The preimage of α in the exact sequence

$$1 \rightarrow \mathcal{O}_C^\times \rightarrow M_C^{\text{gp}} \rightarrow \bar{M}_C^{\text{gp}} \rightarrow 1$$

defines an associated $\mathbb{G}_m$ -torsor $\mathcal{O}^\times(\alpha)$, which we compactify to a line bundle $\mathcal{O}(\alpha)$ by glueing in the ∞ section (this is just a choice of sign; it corresponds to $\mathcal{O}(-p)$ being an ideal sheaf, rather than its dual).

The bundle $\mathcal{O}(\alpha)$ always has total degree 0 but rarely multidegree $\underline{0}$; more precisely, it has multidegree $\underline{0}$ if and only if $\mathcal{O}(\alpha)$ is a pullback from S , which holds if and only if α is constant on geometric fibres.

4.2 Defining LogDR

Before defining the logarithmic double ramification cycle, it seems useful to summarise the construction of the ‘usual’ double ramification cycle from [BHP⁺20]. Various constructions of double ramification cycles are given in various places in the literature in various levels of generality (for

¹¹It would be cleaner to work with vertical (‘unmarked’) log curves, but we will make use of smooth sections of C/S in other places in our arguments, so we do not wish to impose verticality.

example, [Hol21, MW20, HKP18, MW18, BHP⁺20]). They are mostly¹² equivalent, but descriptions of the relations between the constructions are scattered across various sketches in various papers at various levels of generality,¹³ making it troublesome to assemble a complete picture. Here we attempt to rectify this by giving a precise and general statement of the relation between the two most widely used definitions, that of the first-named author by resolving rational maps, and that of Marcus and Wise via tropical divisors (in the form used in [BHP⁺20]).

4.2.1 Tropical divisors. If C/S is a log curve and α a strict piecewise-linear function on C , then the line bundle $\mathcal{O}_C(\alpha)$ determines a map $S \rightarrow \mathfrak{Jac}$. In this way we have an Abel–Jacobi map from the stack of pairs $(C/S, \alpha)$ to $\mathfrak{Jac}$. We can see this Abel–Jacobi map as a first approximation of the double ramification cycle, but the map has relative dimension 1 (a section α admits no non-trivial automorphisms, whereas the line bundle $\mathcal{O}_C(\alpha)$ has a $\mathbb{G}_m$ worth of automorphisms) and hence will not induce a good Chow class on $\mathfrak{Jac}$. To fix this, we need a little more set-up. Given a log scheme $S = (S, M_S)$, we write

$$\mathbb{G}_m^{\text{trop}}(S) = \Gamma(S, \bar{M}_S^{\text{gp}}),$$

which we call the tropical multiplicative group; it can naturally be extended to a presheaf on the category $\mathbf{LSch}_S$ of log schemes over S . A *tropical line* on S is a $\mathbb{G}_m^{\text{trop}}$ torsor on S for the strict étale topology. If C/S is a log curve, P a tropical line on S , $\alpha: C \rightarrow P$ a morphism over S with vanishing outgoing slopes, and $u: U \rightarrow S$ a map such that u^*P is trivial, then a choice of trivialisation $h: u^*P \xrightarrow{\sim} \mathbb{G}_m^{\text{trop}}$ determines a line bundle $\mathcal{O}_U(h \circ \alpha)$. A different trivialisation h' will determine a line bundle $\mathcal{F}$ on S and an isomorphism $\mathcal{O}_U(h \circ \alpha) \xrightarrow{\sim} \mathcal{F} \otimes \mathcal{O}_U(h' \circ \alpha)$. We write $[\mathcal{O}_S(\alpha)]$ for the corresponding S -point of $\bar{\mathbf{J}}$ (noting that in general a representing line bundle $\mathcal{O}_S(\alpha)$ might not exist globally on S).

A point of $\mathbf{Div}$ is a quadruple

$$(C/S, P, \alpha, \mathcal{L}),$$

where C/S is a log curve, P on S a tropical line, $\alpha: C \rightarrow P$ a morphism over S with zero outgoing slopes, and $\mathcal{L}$ a line bundle on C which represents the class $[\mathcal{O}_S(\alpha)]$. The Abel–Jacobi map $\text{aj}: \mathbf{Div} \rightarrow \mathfrak{Jac}$ sends $(C/S, P, \alpha, \mathcal{L})$ to $\mathcal{L}$.

In [BHP⁺20] we defined $\text{DR} \in \text{CH}(\mathfrak{Jac})$ to be the fundamental class of the proper log monomorphism $\mathbf{Div} \rightarrow \mathfrak{Jac}$ (we describe this in more detail in Definition 4.4).

4.2.2 Universal σ -extending morphisms. Over the locus of irreducible curves in $\mathfrak{Jac}$, the notions of total degree and multidegree coincide, so that $\mathbf{J}$ comes with a tautological map from $\mathfrak{Jac}$. We can think of this as a rational map

$$\sigma: \mathfrak{Jac} \dashrightarrow \mathbf{J}$$

(rational because it is only defined on the open locus of irreducible curves).

Let $t: T \rightarrow \mathfrak{Jac}$ be a map of algebraic stacks over $\mathfrak{M}$. We say t is σ -*extending* if

- (i) the pullback along t of the locus of line bundles on smooth curves is schematically dense in T ;

¹²With the exception of classes given by the closure of the double ramification locus on the moduli space of smooth curves, as for example in the theory of admissible cover compactifications.

¹³This is in fairly large part the responsibility of the first-named author.

- (ii) the rational map $T \dashrightarrow J$ induced by σ extends to a morphism (necessarily unique if it exists, by the separatedness of J over $\mathfrak{M}$).

One can then show just as in [Hol21] that the category of σ -extending stacks over $\mathfrak{Jac}$ has a terminal object, which we denote by $\mathfrak{Jac}^\diamond$. The natural map

$$f: \mathfrak{Jac}^\diamond \rightarrow \mathfrak{Jac} \quad (4.2.1)$$

is separated, relatively representable by algebraic spaces, of finite presentation, and an isomorphism over the locus of smooth (even treelike) curves, but it is not in general proper. The construction equips it with a map

$$\sigma: \mathfrak{Jac}^\diamond \rightarrow J. \quad (4.2.2)$$

Remark 4.3. The analogous definition in [Hol21] had the additional assumption that T be normal. At the time this was needed in order to be able to apply [Hol19, Theorem 4.1] at a certain critical step in the arguments, but since then Marcus and Wise have proven the analogue of [Hol19, Theorem 4.1] with no regularity assumptions; see [MW20, Corollary 3.6.3]. This can then be used to modify the theory of [Hol21] without a normality assumption. Alternatively, one can reinstate the condition that T be normal, and all of the subsequent discussion will go through unchanged except that we will have to insert normalisations in various places. By Costello's theorem [HW21], this will have no effect on the resulting cycles but will make things much less readable, which is why we prefer to omit the condition.

4.2.3 The functor of points of $\mathfrak{Jac}^\diamond$. One can describe the functor of points (on the category of log schemes) of $\mathfrak{Jac}^\diamond$ in a manner very similar to the definition of **Div**. Namely, a point of $\mathfrak{Jac}^\diamond$ is a quadruple

$$(C/S, P, \alpha, \mathcal{L}),$$

where C/S is a log curve, P a tropical line on S , $\alpha: C \rightarrow P$ a morphism over S with zero outgoing slopes, and $\mathcal{L}$ a line bundle on C such that the class $[\mathcal{L} \otimes \mathcal{O}_C(-\alpha)]$ has *multidegree 0* on every fibre of C/S .

With this description, the open immersion from the logic of multidegree 0 line bundles in $\mathfrak{Jac}$ to $\mathfrak{Jac}^\diamond$ sends a pair $(C/S, \mathcal{L})$ to $(C/S, \mathbb{G}_m^{\text{trop}}, 0, \mathcal{L})$; that is, we take the sPL function α to be the constant function 0.

Given such a $(C/S, P, \alpha, \mathcal{L})$, the map $S \rightarrow J$ given by $[\mathcal{L} \otimes \mathcal{O}_C(-\alpha)]$ is an extension of σ , so by the universal property of $\mathfrak{Jac}^\diamond$, we obtain a map from the stack of such quadruples to $\mathfrak{Jac}^\diamond$. To show that this is an isomorphism, we may work locally (so assume C/S to be nuclear in the sense of [HMOP20] and smooth over a dense open of S); it is then enough to show that the extension of σ is given by an sPL function, but this follows from [MW20, Corollary 3.6.3].

4.2.4 Comparison. The key actor in Section 3.5 is the fibre product of the diagram

$$\begin{array}{ccc} & \mathfrak{M} & \\ & \downarrow e & \\ \mathfrak{Jac}^\diamond & \xrightarrow{\sigma} & J. \end{array}$$

From the functor-of-points description of $\mathfrak{Jac}$, this fibre product is exactly given by tuples $(C/S, P, \alpha, \mathcal{L}) \in \mathfrak{Jac}^\diamond$ such that $[\mathcal{L} \otimes \mathcal{O}_C(-\alpha)]$ is trivial; that is, $\mathcal{L}$ represents the class $[\mathcal{O}_C(\alpha)]$.

In other words, we have a pullback square

$$\begin{array}{ccc} \mathbf{Div} & \longrightarrow & \mathfrak{M} \\ \downarrow & & \downarrow e \\ \mathfrak{Jac}^\diamond & \xrightarrow{\sigma} & \mathbf{J}. \end{array}$$

Marcus and Wise show that the composite $\mathbf{Div} \rightarrow \mathfrak{Jac}$ is proper, and in [BHP⁺20] we define DR to be the associated cycle on $\mathfrak{Jac}$. The full construction of the operational class is a little subtle (see [BHP⁺20, § 2] for details) but is easy to describe for a smooth stack S mapping to $\mathfrak{Jac}$.

DEFINITION 4.4. Let S be a smooth stack and $\varphi: S \rightarrow \mathfrak{Jac}$ a morphism. Then φ is lci, so we have a gysin pullback $\varphi^!: A^*(\mathbf{Div}) \rightarrow A^*(\mathbf{Div} \times_{\mathfrak{Jac}} S)$ and, following [Sko12], a proper pushforward $i_*: A^*(\mathbf{Div} \times_{\mathfrak{Jac}} S) \rightarrow A^*(S)$. Since S is smooth, the intersection pairing furnishes a map $\cap: A^*(S) \rightarrow \mathrm{CH}(S)$, and we define

$$\varphi^* \mathrm{DR} = \cap(i_* \varphi^! [\mathbf{Div}]) \in \mathrm{CH}(S),$$

where $[\mathbf{Div}]$ denotes the fundamental class of $\mathbf{Div}$ as a cycle on itself.

4.2.5 *Defining LogDR.* We construct the cycle LogDR in $\mathrm{LogCH}(\mathfrak{Jac})$ as hinted at in [BHP⁺20, § 3.8]. We apply the construction of Section 3.5, taking $S = \mathfrak{Jac}$, $X = \mathfrak{Jac}^\diamond$, $\mathbf{J} = \mathbf{J}$, and $\sigma = \sigma$. We need the natural map

$$\mathfrak{Jac}^\diamond \times_{\mathbf{J}} \mathfrak{M} \rightarrow \mathfrak{Jac}$$

to be proper; this can be proven in the same way as in [Hol21, § 5] or follows by the comparison to the construction of Marcus–Wise in Section 4.2.4.

DEFINITION 4.5. The construction in Section 3.5 yields a class $\mathrm{LogDR} := [\sigma^* e]_{f, \log} \in \mathrm{LogCH}(\mathfrak{Jac})$, the *log double ramification cycle*.

Comparing the constructions yields the following.

LEMMA 4.6. Applying the pushforward $\nu_*: \mathrm{LogCH}(\mathfrak{Jac}) \rightarrow \mathrm{CH}(\mathfrak{Jac})$ of Definition 2.13 to $\mathrm{LogDR} \in \mathrm{LogCH}(\mathfrak{Jac})$ recovers the double ramification cycle $\mathrm{DR} \in \mathrm{CH}(\mathfrak{Jac})$ of [BHP⁺20].

Proof. The class $\mathrm{DR} \in \mathrm{CH}(\mathfrak{Jac})$ can be obtained by applying Definition 4.4 to the smooth stack $S = \mathfrak{Jac}$ (with the map $\varphi: \mathfrak{Jac} \rightarrow \mathfrak{Jac}$ being the identity), so we need to compare this to the construction in Section 3.5. We will begin by making a slight simplifying assumption, namely that $X = \mathfrak{Jac}^\diamond$ can be embedded in a smooth log blowup $\tilde{S} = \mathfrak{Jac}^\blacklozenge$ of S (in other words, that we can take $\tilde{X} = X$). Then we have a commutative diagram with cartesian square

$$\begin{array}{ccc} \mathbf{Div} & \longrightarrow & \mathfrak{M} \\ \downarrow & & \downarrow e \\ \mathfrak{Jac}^\diamond & \xrightarrow{\sigma} & \mathbf{J} \\ \downarrow & & \\ \mathfrak{Jac}^\blacklozenge & & \\ \downarrow & & \\ \mathfrak{Jac}. & & \end{array}$$

Now $\nu_* \text{LogDR}$ is by definition the pushforward to $\mathfrak{Jac}$ of the class $e^! [\mathfrak{Jac}^\diamond]$ on $\mathbf{Div}$, so it suffices to show that $e^! [\mathfrak{Jac}^\diamond]$ is equal to the fundamental class of $\mathbf{Div}$. But $e^!$ takes the fundamental class to the fundamental class, so this is clear.

What if we cannot embed $\mathfrak{Jac}^\diamond$ in a smooth log blowup $\mathfrak{Jac}^\blacklozenge$ of $\mathfrak{Jac}$? Then we must first replace $\mathfrak{Jac}^\diamond$ with some log blowup of itself. The argument then proceeds as above, with the additional input that replacing $\mathbf{Div}$ by a log blowup does not change the class of the final pushforward to $\mathfrak{Jac}$. $\square$

4.3 Invariance of LogDR in twistable families

Throughout this subsection, C/S is a log curve over a smooth log smooth base, and $\mathcal{L}$ is a line bundle on C .

DEFINITION 4.7. We say that the pair $(C/S, \mathcal{L})$ is *twistable* if there exists an sPL function α on C such that $\mathcal{L}(\alpha)$ has multidegree $\mathbf{0}$; we call such an α a *twisting function*.

Being twistable is equivalent to the existence of a Cartier divisor on D on C supported over the boundary of S and such that $\mathcal{L}(D)$ has multidegree $\mathbf{0}$; see [Hol19, Theorem 4.1] or [MW20, Corollary 3.6.3].

LEMMA 4.8. Let $(C/S, \mathcal{L})$ be twistable with α a twisting function. Write $\varphi_{\mathcal{L}}: S \rightarrow \mathfrak{Jac}$ for the map induced by $\mathcal{L}$ and $\varphi_{\mathcal{L}(\alpha)}: S \rightarrow \mathfrak{Jac}$ for the map induced by $\mathcal{L}(\alpha)$. Then

$$\varphi_{\mathcal{L}}^* \text{LogDR} = \varphi_{\mathcal{L}(\alpha)}^* \text{DR}$$

in $\text{LogCH}(S)$ (where we view $\varphi_{\mathcal{L}(\alpha)}^* \text{DR}$ in $\text{LogCH}(S)$ by pullback; cf. Section 2.2).

Proof. Write $\sigma: S \dashrightarrow J$ for the rational map induced by $\mathcal{L}$. Then the identity on S is the universal σ -extending morphism! More precisely, the extension is given by $\mathcal{L}(\alpha): S \rightarrow J$, and it is easily seen to be universal among extensions (see Remark 4.9). We have a pullback diagram

$$\begin{array}{ccc} S \times_J e & \longrightarrow & e \\ \downarrow j & & \downarrow i \\ S & \xrightarrow{\sigma} & J, \end{array}$$

and the definitions of $\varphi_{\mathcal{L}}^* \text{LogDR}$ and $\varphi_{\mathcal{L}(\alpha)}^* \text{DR}$ simplify to

$$\varphi_{\mathcal{L}}^* \text{LogDR} = j_* i^! [S] \quad \text{and} \quad \varphi_{\mathcal{L}(\alpha)}^* \text{DR} = j_* \sigma^! [e],$$

which are equal since $\sigma^! [e] = i^! [s]$ (commutativity of the intersection pairing). $\square$

Remark 4.9. If $(C/S, \mathcal{L})$ is twistable, then α is not unique, but the line bundle $\mathcal{L}(\alpha)$ is uniquely determined up to pullback from S . Hence $\varphi_{\mathcal{L}(\alpha)}^* \text{DR}$ does not depend on the choice of α .

Remark 4.10. Unfortunately, the notion of twistable families seems a little too restrictive; not enough of them seem to exist to determine LogDR from DR (though we have not written down a proof). Because of this, we now introduce a weaker notion.

DEFINITION 4.11. We say $(C/S, \mathcal{L})$ is *almost twistable* if there exist an sPL function α on C and a dense open $i: U \hookrightarrow S$ such that:

- (i) the restriction of α to U is a twisting function;
- (ii) the map $U \xrightarrow{i \times \varphi_{\mathcal{L}(\alpha)}} S \times_{\mathfrak{M}} J$ is a closed immersion (equivalently, its image is closed).

We give some alternative formulations of the second condition in Definition 4.11, which will be used in the proof of Lemma 4.18.

LEMMA 4.12. *Suppose that we are given $(C/S, \mathcal{L})$, an sPL function α on C , and a dense open $U \hookrightarrow S$ such that the restriction of α to U is a twisting function. Then the following are equivalent:*

- (i) *The map $U \xrightarrow{i \times \varphi_{\mathcal{L}(\alpha)}} S \times_{\mathfrak{M}} J$ is a closed immersion (that is, $(C/S, \mathcal{L})$ is almost twistable).*
- (ii) *For any trait T with generic point η and any map $T \rightarrow S$ sending η to a point in U , if the map $\eta \rightarrow S \times_{\mathfrak{M}} J$ induced by $\mathcal{L}(\alpha)$ can be extended to a map $T \rightarrow S \times_{\mathfrak{M}} J$, then the map $T \rightarrow S \times_{\mathfrak{M}} J$ factors via $U \xrightarrow{i \times \varphi_{\mathcal{L}(\alpha)}} S \times_{\mathfrak{M}} J$. (A trait is the spectrum of a discrete valuation ring.)*
- (iii) *For any trait T with generic point η and any map $T \rightarrow S$ sending η to a point in U , if the map $\eta \rightarrow J$ induced by $\mathcal{L}(\alpha)$ can be extended to a map $T \rightarrow J$, then the map $T \rightarrow S$ factors via U .*

Proof. Condition (ii) is exactly the valuative criterion for properness for $U \xrightarrow{i \times \varphi_{\mathcal{L}(\alpha)}} S \times_{\mathfrak{M}} J$; hence conditions (i) and (ii) are equivalent.

The difference between conditions (ii) and (iii) is about whether we allow the underlying curve to change when we construct an extension of the line bundle, but in fact this makes no difference, by Lemma 4.13. $\square$

LEMMA 4.13. *Let T be a trait with generic point η , and let C, C' be prestable curves over T . Let $\varphi: C_{\eta} \rightarrow C'_{\eta}$ be an isomorphism over η . Write J for the multidegree 0 jacobian of C/T (so J is the pullback of J along the classifying map $T \rightarrow \mathfrak{M}$ of C), and similarly define J' from C' . Then the isomorphism $J_{\eta} \xrightarrow{\sim} J'_{\eta}$ induced by φ extends uniquely to a T -isomorphism $J \xrightarrow{\sim} J'$.*

It is easy to see that the fibres of J and J' over the closed point t of T are isomorphic, since C_t and C'_t just differ by inserting some chains of rational curves at nodes and adding some rational tails (see the explicit description of J_t in [BLR90, Example 9.2.8]). However, this is not enough; we need a (unique) global isomorphism compatible with φ .

Proof. This follows from the uniqueness of semiabelian prolongations over normal noetherian bases in [Ray70, Chapter XI, § 1.15]. The result is stated there in the case where the generic fibre C_{η} is of compact type (so J_{η} is abelian), but the proof goes through unchanged if one allows arbitrary prestable curves and replaces Néron models of abelian schemes with Néron lft-models of semiabelian schemes. $\square$

LEMMA 4.14. *Let $(C/S, \mathcal{L})$ be almost twistable with α a twisting function. Write $\varphi_{\mathcal{L}}: S \rightarrow \mathfrak{Jac}$ for the map induced by $\mathcal{L}$ and $\varphi_{\mathcal{L}(\alpha)}: S \rightarrow \mathfrak{Jac}$ for the map induced by $\mathcal{L}(\alpha)$. Then*

$$\varphi_{\mathcal{L}}^* \text{LogDR} = \varphi_{\mathcal{L}(\alpha)}^* \text{DR}$$

in $\text{LogCH}(S)$.

Proof. Write $\sigma: S \dashrightarrow J$ for the rational map induced by $\mathcal{L}$. Then the inclusion $U \hookrightarrow S$ is the universal σ -extending morphism. More precisely, the extension is given by $\mathcal{L}(\alpha): U \rightarrow J$, and the second property of Definition 4.11 shows it to be universal among extensions. Since $\mathcal{L}(\alpha)$ is of total degree 0 over the whole of S , it defines a map $\bar{\sigma}: S \rightarrow \bar{J}$ over the whole of S . Consider the

diagram

$$\begin{array}{ccc}
 U \times_J e & \longrightarrow & e \\
 \downarrow & & \downarrow i \\
 U & \xrightarrow{\sigma} & J \\
 \downarrow & & \downarrow \\
 S & \xrightarrow{\bar{\sigma}} & \bar{J},
 \end{array}$$

where both squares are pullbacks (the top by construction, the bottom by the defining property of U), so that $U \times_J e = S \times_J e$. In the notation of Section 3.5, we take $S = \tilde{S}$ and $X = \tilde{X} = U$. Then the definitions of $\varphi_{\mathcal{L}}^* \text{LogDR}$ and $\varphi_{\mathcal{L}(\alpha)}^* \text{DR}$ simplify to

$$\varphi_{\mathcal{L}}^* \text{LogDR} = j_* i^! [U] \quad \text{and} \quad \varphi_{\mathcal{L}(\alpha)}^* \text{DR} = j_* \bar{\sigma}^! [e] = j_* \sigma^! [e],$$

which are equal by the commutativity of the intersection pairing. $\square$

The hard work remaining in this paper is to show that there are ‘enough’ almost-twistable families for Lemma 4.14 to determine LogDR from DR.

4.4 Extending piecewise-linear functions

Let C/S be a log curve. The key to showing the existence of enough almost-twistable families will be to extend strict piecewise-linear functions over open subsets of S to strict piecewise-linear functions over the whole of S , perhaps after some monoidal alteration.

LEMMA 4.15. *Let C/S be a log curve with S a smooth log algebraic stack. Then there exist*

- (i) *a monoidal alteration $\tilde{S} \rightarrow S$;*
- (ii) *a subdivision $\tilde{C} \rightarrow C \times_S \tilde{S}$*

with $\tilde{C}/\tilde{S}$ a log curve and $\tilde{C}$ regular.

Proof. This follows from [ALT19]. More precisely, their Theorem 4.4 gives a canonical monoidal resolution over schemes, which therefore applies to stacks. The argument in the proof of their Theorem 4.5 then shows that this monoidal resolution has $\tilde{C}$ regular. $\square$

After applying Lemma 4.15, we will show that sPL functions always extend. We start by considering the case where the base S is very small (*nuclear* in the sense of [HMOP20]), after which we will glue to a global solution.

LEMMA 4.16. *Let C/S be a regular log curve over a (regular) log regular base, with C/S nuclear. Let $U \hookrightarrow S$ be strict dense open, and let α be an sPL function on C_U/U . Then we can construct an extension $\bar{\alpha}$ to an sPL function on C/S , and this construction is compatible with strict open base-change.*

Proof. Let s be the generic point of the closed stratum of S . Let r be the rank of $\bar{M}_{S,s}$, and let $D_1, \dots, D_r$ be the divisorial strata of the boundary of S . Let Γ be the graph of C/S over the closed stratum, and let Γ_i be the graph over the generic point of D_i (obtained by contracting those edges of Γ whose lengths differ from D_i). Our assumption that C/S be nuclear implies that S is simple (equivalently, every intersection of D_i s is regular and connected) and moreover that the intersection of *all* of the D_i is non-empty.

On each D_i with non-empty intersection with U , we equip Γ_i with the sPL function from α , and for the other D_i , we put the zero sPL function.

Now let z be a stratum of S , with graph Γ_z , and let $N_z \subseteq \{1, \dots, r\}$ be such that $\overline{\{z\}} = \bigcap_{i \in N_z} D_i$. Then by (3.2.4), we have $\bar{M}_{S,z} = \bigoplus_{i \in N_z} \mathbb{N} \cdot D_i$; write $f_i: \mathbb{N} \cdot D_i \rightarrow \bar{M}_{S,z}$ for the natural inclusion. Let v be a vertex of Γ_z , and for each $i \in N_z$, let v_i be its image in Γ_i under specialisation. Then we define

$$\bar{\alpha}(v) = \sum_{i \in N_z} f_i(\alpha(v_i)).$$

To check that $\bar{\alpha}$ is an sPL function on Γ_z , suppose that e is an edge of Γ_z between vertices u and v . By the regularity of C , we know that the length of e is D_i for some $i \in N_z$; suppose that it is D_1 . Then $f_i(u) = f_i(v)$ for every $i \neq 1$, and $D_1 \mid \alpha(f_1(u)) - \alpha(f_1(v))$. It is easy to see that $\bar{\alpha}$ restricts to α over U .

Suppose that $S' \rightarrow S$ is a strict open map such that $C_{S'}/S'$ is also nuclear and $C_{S'}$ is regular. Let s' be the generic points of the closed stratum of S' ; it is enough to check the result for the restriction of $\bar{\alpha}$ to $\Gamma_{s'}$. Let $N' \subseteq \{1, \dots, r\}$ be the set of those D_i meeting the image of s' . Then all of those D_i meet the image of S' , and their pullbacks are exactly the divisorial strata on S' (so in particular the rank of $\bar{M}_{S',s'}$ is $\#N'$). Then $\bar{\alpha}$ on $\Gamma_{s'}$ is constructed by interpolating the values of α on the D_i for $i \in N'$, regardless of whether we compute this on S or on S' ; in particular, these give the same result. $\square$

LEMMA 4.17. *Let C/S be a log curve with C (and hence S) regular log regular, and S a log algebraic stack. Let $U \hookrightarrow S$ be a strict dense open immersion and α an sPL function on C_U . Then there exists an sPL function $\bar{\alpha}$ on S restricting to α .*

Proof. By [HMOP20, Lemma 3.40], we know that S admits a strict étale cover $\{S_i\}_i \rightarrow S$ with each $C \times_S S_i/S_i$ nuclear. In Lemma 4.16, we give a canonical choice of extension for each $C \times_S S_i/S_i$, and these are compatible with smooth base-change, so descend to algebraic stacks. $\square$

4.5 LogDR from DR

We wish to compute LogDR in $\text{LogCH}(\mathfrak{Jac})$. Let $i: S \hookrightarrow \mathfrak{Jac}$ be a strict open immersion with S quasi-compact, and write C/S for the universal curve and $\mathcal{L}$ on C for the universal line bundle.

LEMMA 4.18. *There exist*

- (i) *a monoidal alteration $\psi: \tilde{S} \rightarrow S$;*
- (ii) *a subdivision $\tilde{C}$ of $C \times_S \tilde{S}$*

such that the pair $(\tilde{C}/\tilde{S}, \psi^\mathcal{L})$ is almost twistable.*

Proof. Write $\sigma: S \dashrightarrow J$ for the rational map induced by $\mathcal{L}$, and let $\psi_1: S^\diamond \rightarrow S$ be the universal σ -extending morphism.

CLAIM. There exists a representable monoidal alteration $S^{\diamond\diamond}$ of $S^\diamond$ over which the map $\sigma: S^\diamond \rightarrow J$ can be represented as $\psi_1^*\mathcal{L}(\alpha)$ for some sPL function α over $S^{\diamond\diamond}$.

The claim is clear from Section 4.2.3 locally on $S^\diamond$, but these sPL functions are only unique up to addition of an sPL function from the base and so need not glue. We define $S^{\diamond\diamond}$ to be the subfunctor of $S^\diamond$ where the maps $\alpha: C \rightarrow P$ (in the notation of Section 4.2.3) can be chosen such that their set of values is totally ordered (in the ordering on P induced by the monoid structure

on $\bar{M}^{\text{gp}}$). That this subfunctor is a representable monoidal alteration of $S^\diamond$ is proven exactly as in [MW20, Theorem 5.3.4] for the map $\mathbf{Rub} \rightarrow \mathbf{Div}$, to which it is closely analogous.

Now we can construct these α locally on $S^{\diamond\diamond}$ just as before, but with $P = \mathbb{G}_M^{\text{trop}}$ and the additional requirement that the smallest value taken by α on any vertex is zero. This makes the α unique; hence they glue to a global sPL function, proving the claim.

Now let $S^\diamond \rightarrow S$ be a sufficiently fine log blowup for $S^{\diamond\diamond} \rightarrow S$, and let $U \hookrightarrow S^\diamond$ be the lift of $S^{\diamond\diamond}$.

Writing $C^\diamond/S^\diamond$ for the pullback of C/S , we apply Lemma 4.15 to the $C^\diamond/S^\diamond$ to construct a monoidal alteration $\tilde{S} \rightarrow S^\diamond$ and a subdivision $\tilde{C}$ of $C^\diamond \times_{S^\diamond} \tilde{S} = C \times_S \tilde{S}$ with $\tilde{C}$ (and hence $\tilde{S}$) regular. Writing $\psi: \tilde{S} \rightarrow S$ for the composite, we claim that the pair $(\tilde{C}/\tilde{S}, \psi^*\mathcal{L})$ is almost twistable.

Let $\tilde{U}$ be the pullback of U to $\tilde{S}$ (a twistable open), and let α be a twisting function over $\tilde{U}$. Then Lemma 4.17 implies that this α can be extended to an sPL function over the whole of $\tilde{S}$.

Now let $T \rightarrow S$ be a trait with generic point η landing in $\tilde{U}$. Suppose that the map $\eta \rightarrow J$ is given by $(\psi_1^*\mathcal{L})(\alpha)$; then it is proven in [Hol21, Lemma 4.3] that this cannot be extended to a map $T \rightarrow J$ unless it can already be extended to a map $T \rightarrow U$. By Lemma 4.12, this shows that $(\tilde{C}/\tilde{S}, \psi^*\mathcal{L})$ is almost twistable, with $\tilde{U} \hookrightarrow \tilde{S}$ the largest twistable open. $\square$

Let $(\tilde{C}/\tilde{S}, \psi^*\mathcal{L})$ be as in the statement of Lemma 4.18, with twisting function α over $\tilde{S}$. Then we have maps

$$\varphi_{\mathcal{L}}: \tilde{S} \rightarrow \mathfrak{Jac} \quad \text{and} \quad \varphi_{\mathcal{L}(\alpha)}: \tilde{S} \rightarrow \mathfrak{Jac}$$

induced by $\psi^*\mathcal{L}$ and $\psi^*\mathcal{L}(\alpha)$, respectively.

THEOREM 4.19. *We have an equality of cycles $\varphi_{\mathcal{L}}^* \text{LogDR} = \varphi_{\mathcal{L}(\alpha)}^* \text{DR}$ in $\text{LogCH}(S)$.*

Proof. This is immediate from Lemmas 4.14 and 4.18. $\square$

4.6 LogDR is tautological

If $\mathcal{L}$ is the universal line bundle on the universal curve $\pi: C \rightarrow \mathfrak{Jac}$, we define the class

$$\eta = \pi_*(c_1(\mathcal{L})^2) \in \text{CH}(\mathfrak{Jac}). \quad (4.6.1)$$

In [BHP⁺20, Definition 4], we defined a tautological subring of $\text{CH}(\mathfrak{Jac})$. It is the $\mathbb{Q}$ -span of certain decorated prestable graphs of degree 0, as described in [BHP⁺20, § 0.3.3]; in particular, it includes the class η from (4.6.1). Here we prove that LogDR is contained in the corresponding tautological subring of $\text{LogCH}(\mathfrak{Jac})$. In fact, we can prove something stronger.¹⁴ We write $\mathbb{Q}[\eta] \subseteq \text{CH}(\mathfrak{Jac})$ for the sub- $\mathbb{Q}$ -algebra of the Chow ring generated by the class η of (4.6.1) and recall from Definition 3.18 that $\mathbb{Q}[\eta]^{\text{log}}$ denotes the corresponding subring of $\text{LogCH}(\mathfrak{Jac})$; we show that LogDR lies in $\mathbb{Q}[\eta]^{\text{log}}$.

Continuing in the notation of the previous subsection, we can pull back $\mathbb{Q}[\eta]^{\text{log}}$ along $\varphi_{\mathcal{L}}: S \rightarrow \mathfrak{Jac}$ to give a subring of $\text{LogCH}(S)$. Since $\varphi_{\mathcal{L}}$ is strict, this is equivalent to pulling back $\mathbb{Q}[\eta] \subseteq \text{CH}(\mathfrak{Jac})$ to $\text{CH}(S)$, then taking the corresponding subring of $\text{LogCH}(S)$. We denote the resulting subring by $\mathbb{Q}[\eta]_S^{\text{log}} \subseteq \text{LogCH}(S)$.

LEMMA 4.20. *Suppose that k has characteristic 0. In the notation of Theorem 4.19, the cycle $\varphi_{\mathcal{L}(\alpha)}^* \text{DR}$ lies in $\mathbb{Q}[\eta]_S^{\text{log}} \subseteq \text{LogCH}(S)$.*

¹⁴This improvement was suggested to us by Johannes Schmitt, to whom we are very grateful for permission to include it.

We are grateful to Johannes Schmitt for pointing out an omission in an earlier version of the proof (as well as the strengthening mentioned above).

Proof. This is an easy consequence of Pixton's formula for DR on $\mathfrak{Jac}^\diamond$, as stated in equation (56) of [BHP⁺20, § 0.7]. The formula expresses DR as a polynomial in the following classes:

- (i) the class $\pi_*(c_1(\psi^*\mathcal{L}(\tilde{\alpha}))^2)$;
- (ii) classes $\psi_h + \psi_{h'}$, where h, h' are the two half-edges forming an edge of a graph of $C/\tilde{S}$.

It hence suffices to show that the above classes lie in $\mathbb{Q}[\eta]_S^{\log}$; we treat them in order:

- (i) The class $\pi_*(c_1(\psi^*\mathcal{L}(\tilde{\alpha}))^2)$ can be expanded as a sum

$$\pi_*(c_1(\psi^*\mathcal{L})^2) + 2\pi_*(c_1(\psi^*\mathcal{L})c_1(\mathcal{O}_C(\tilde{\alpha}))) + \pi_*(c_1(\mathcal{O}_C(\tilde{\alpha}))^2).$$

The first summand is the pullback of the tautological class $\eta = \pi_*(c_1(\mathcal{L})^2)$ from $\text{CH}(\mathfrak{Jac})$, hence is in $\mathbb{Q}[\eta]_S^{\log}$. For the second summand, we can reduce to computing $\pi_*(c_1(\psi^*\mathcal{L})D)$, where D is some vertical prime divisor on $C/\tilde{S}$, say with image a prime divisor Z on $\tilde{S}$. Then for dimension reasons, we see that $\pi_*(c_1(\psi^*\mathcal{L})D)$ is an integer multiple of the class of the boundary divisor Z , in particular is in $\mathbb{Q}[\eta]_S^{\log}$.

Finally, the class $c_1(\mathcal{O}_C(\tilde{\alpha}))$ can be written as a sum of vertical boundary divisors on $C/\tilde{S}$. If D and E are distinct vertical prime divisors, then D and E meet properly, and their locus of intersection is a union of vertical codimension 2 loci in C (which push down to zero on $\tilde{S}$ for dimension reasons) and horizontal boundary strata which push forward to boundary classes on $\tilde{S}$.

It remains to show that $\pi_*(D^2)$ is tautological. For this, let Z be the prime divisor in $\tilde{S}$ which is the image of D , and let E be the vertical divisor lying over Z such that $\pi^*Z = D + E$. Then $\pi_*(D^2) = \pi_*(D \cdot (\pi^*Z - E)) = \pi_*(D \cdot E)$, which reduces us to the previous case.

- (ii) These are exactly the first Chern classes of conormal bundles to boundary divisors on $\tilde{S}$. As such they can be realised as self-intersections of these boundary divisors (perhaps after a harmless further blowup we may assume $\tilde{S}$ simple), hence are in $\mathbb{Q}[\eta]_S^{\log}$. $\square$

Putting together Theorem 4.19 and Lemma 4.20, we obtain the following.

COROLLARY 4.21. *Suppose that k has characteristic 0. Write $T \subseteq \text{CH}(\mathfrak{Jac})$ for the tautological ring as in [BHP⁺20, Definition 4] and $\mathbb{Q}[\eta] \subseteq T$ for the subring generated by the class η from (4.6.1). Then the class $\text{LogDR} \in \text{LogCH}(\mathfrak{Jac})$ lies in $\mathbb{Q}[\eta]_S^{\log} \subseteq T^{\log}$.*

4.7 Conjecture C

In this section, we prove Conjecture C of [MPS21]; we thank Johannes Schmitt and the anonymous referee for corrections and improvements to this argument. Given non-negative integers g, n satisfying $2g - 2 + n > 0$, we write $\overline{\mathcal{M}}_{g,n}$ for the corresponding stack of stable marked curves, with log structure given by the boundary divisor. We write $R_{g,n}$ for the subring of $\text{LogCH}(\overline{\mathcal{M}}_{g,n})$ generated by the classes $\psi_1, \dots, \psi_n$ and the boundary divisors of logarithmic blowups of $\overline{\mathcal{M}}_{g,n}$.

Let $a_1, \dots, a_n$ be integers summing to 0, where $p_1, \dots, p_n$ are the markings on the universal curve $C_{g,n}/\overline{\mathcal{M}}_{g,n}$. Write $\varphi_a: \overline{\mathcal{M}}_{g,n} \rightarrow \mathfrak{Jac}$ for the map induced by $\mathcal{O}_{C_{g,n}}(\sum_i a_i p_i)$.

THEOREM 4.22 ([MPS21, Conjecture C]). *Suppose that k is a field of characteristic 0. Then $\varphi_a^* \text{LogDR}$ lies in $R_{g,n} \subseteq \text{LogCH}(\overline{\mathcal{M}}_{g,n})$.*

Proof. We know $\text{LogDR} \in \mathbb{Q}[\eta]^{\log}$, and one easily computes $\varphi_a^* \eta = -\sum_i a_i^2 \psi_i$. By definition, there exists a simple log blowup $\widetilde{\mathcal{M}}_{g,n}$ of $\overline{\mathcal{M}}_{g,n}$ on which $\varphi_a^* \text{LogDR}$ is determined; write $t \in \text{CH}(\widetilde{\mathcal{M}}_{g,n})$ for the determination. By Theorem 3.8, there exists a polynomial p in strict piecewise-linear functions on $\widetilde{\mathcal{M}}_{g,n}$ such that $\Phi_{\widetilde{\mathcal{M}}_{g,n}}(p) = t$, where $\Phi_{\widetilde{\mathcal{M}}_{g,n}}$ is the map as in (3.3.2). Now $\Phi_{\widetilde{\mathcal{M}}_{g,n}}$ is a ring homomorphism, and strict piecewise-linear functions map to linear combinations of logarithmic boundary divisors, so the result follows. $\square$

5. The double-double ramification cycle

5.1 Iterated double ramification cycles

Let r be a positive integer, and let $\mathfrak{Jac}^r$ be the fibre product of r copies of $\mathfrak{Jac}$ over $\mathfrak{M}$. This is smooth and log smooth, and comes with r projection maps to $\mathfrak{Jac}$. According to Definition 2.11, we can pull back LogDR along each of the projection maps, yielding r elements of $\text{LogCH}(\mathfrak{Jac}^r)$. We define LogDR_r to be the product of these elements in the ring $\text{LogCH}(\mathfrak{Jac}^r)$.

We can also give a more direct construction of LogDR_r . Write J^r for the r -fold fibre product of J with itself over $\mathfrak{M}$, with e_r the unit section. Then over the locus of smooth curves, we have a tautological morphism $\sigma_r: \mathfrak{Jac}^r \rightarrow J^r$; we view it as a rational map $\sigma_r: \mathfrak{Jac}^r \dashrightarrow J^r$ and let $\mathfrak{Jac}^{r\Diamond}$ be the universal σ_r -extending stack over $\mathfrak{Jac}^r$. The pullback $\sigma_r^* e_r$ is proper over $\mathfrak{M}$, so we can apply the construction in Section 3.5 to obtain a class $[\sigma_r^* e_r]_{\log} \in \text{LogCH}(\mathfrak{Jac}^r)$.

LEMMA 5.1. *These two constructions of LogDR_r coincide; that is, $\text{LogDR}_r = [\sigma_r^* e_r]_{\log}$.*

Proof. We begin by comparing $\mathfrak{Jac}^{r\Diamond}$ with $(\mathfrak{Jac}^\Diamond)^r$, where the latter denotes the r -fold fibre product over $\mathfrak{M}$ in the category of fs log algebraic stacks. The composites $\mathfrak{Jac}^{r\Diamond} \rightarrow J^r \rightarrow J$ are σ -extending; hence the universal property furnishes r maps $\mathfrak{Jac}^{r\Diamond} \rightarrow \mathfrak{Jac}^\Diamond$, hence a map

$$\mathfrak{Jac}^{r\Diamond} \rightarrow (\mathfrak{Jac}^\Diamond)^r \quad (5.1.1)$$

to the fibre product. On the other hand, the fibre product $(\mathfrak{Jac}^\Diamond)^r$ is σ_r -extending, yielding an inverse to (5.1.1). The claimed equality of cycles is then immediate from the construction in Section 3.5 and an application of [Ful84, Example 6.5.2] (whose proof carries over to this setting essentially unchanged). $\square$

Write $\mathcal{L}_1, \dots, \mathcal{L}_r$ for the tautological line bundles on the universal curve over $\mathfrak{Jac}^r$, with corresponding classes

$$\eta_i = \pi_*(c_1(\mathcal{L})^2) \in \text{CH}(\mathfrak{Jac}),$$

and let $\mathbb{Q}[\eta^r]$ denote the sub- $\mathbb{Q}$ -algebra of $\text{CH}(\mathfrak{Jac}^r)$ generated by these classes. From Corollary 4.21 and the first construction of LogDR_r , we obtain the following.

LEMMA 5.2. $\text{LogDR}_r \in \mathbb{Q}[\eta^r]^{\log} \subseteq \text{LogCH}(\mathfrak{Jac}^r)$.

5.2 $\text{GL}_r(\mathbb{Z})$ -invariance

Let G/S be a commutative group scheme and M an $r \times r$ matrix with integer coefficients. Writing $G^{\times_r S}$ for the fibre product of G with itself r times over S , we write

$$[M]: G^{\times_r S} \rightarrow G^{\times_r S}$$

for the endomorphism induced by M . If $M \in \text{GL}_r(\mathbb{Z})$, then this is an automorphism.

Applying this to $\mathfrak{Jac}$ over $\mathfrak{M}$ with $M \in \mathrm{GL}_r(\mathbb{Z})$ yields an automorphism $[M]: \mathfrak{Jac}^r \rightarrow \mathfrak{Jac}^r$, and pulling back along the map yields an automorphism

$$[M]^*: \mathrm{LogCH}(\mathfrak{Jac}^r) \rightarrow \mathrm{LogCH}(\mathfrak{Jac}^r). \quad (5.2.1)$$

THEOREM 5.3. *The map $[M]^*$ of (5.2.1) takes LogDR_r to itself.*

Proof. For this we use the second construction of LogDR_r , going via $\mathfrak{Jac}^{r\Diamond}$. We write $\sigma_r: \mathfrak{Jac}^r \dashrightarrow J^r$, and we write e for the unit section of J^r . We define $\mathfrak{Jac}^{M\Diamond}$ to be the limit (in the fs category) of the solid diagram

$$\begin{array}{ccc} & \mathfrak{Jac}^{r\Diamond} & \xrightarrow{\nu} \mathfrak{Jac}^r \\ & \uparrow s & \downarrow [M] \\ \mathfrak{Jac}^{M\Diamond} & & \\ & \downarrow t & \downarrow \nu \\ & \mathfrak{Jac}^{r\Diamond} & \xrightarrow{\nu} \mathfrak{Jac}^r \end{array}$$

(we can think of $\mathfrak{Jac}^{M\Diamond}$ as the common refinement of $\mathfrak{Jac}^{r\Diamond}$ with its translation along $[M]$). Now the composite $\nu \circ s$ is σ_r -extending, as is the composite $\nu \circ t$, so we obtain a commutative diagram

$$\begin{array}{ccccc} & & \sigma_s & & \\ & & \curvearrowright & & \\ & & \mathfrak{Jac}^r & \dashrightarrow & J^r \\ & \nearrow \nu \circ s & \downarrow [M] & & \downarrow [M] \\ \mathfrak{Jac}^{M\Diamond} & & \mathfrak{Jac}^r & \dashrightarrow & J^r \\ & \searrow \nu \circ t & \downarrow [M] & & \downarrow [M] \\ & & \mathfrak{Jac}^r & \dashrightarrow & J^r \\ & & \sigma_t & & \end{array}$$

Now σ_s^*e is a cycle on $\mathfrak{Jac}^{M\Diamond}$, which can induce (following Section 3.5) a logarithmic cycle on $\mathfrak{Jac}^r$ in two ways; either via the map $\nu \circ s$ or via the map $\nu \circ t$. Our notation is $[\sigma_s^*e]_{\nu \circ s, \log}$ for the former and $[\sigma_s^*e]_{\nu \circ t, \log}$ for the latter, and we define analogously $[\sigma_t^*e]_{\nu \circ s, \log}$ and $[\sigma_t^*e]_{\nu \circ t, \log}$, all elements of $\mathrm{LogCH}(\mathfrak{Jac}_r)$. Applying Lemma 5.1 and the commutativity of the diagram yields the relations

$$\begin{aligned} \mathrm{LogDR}_r &= [\sigma_s^*e]_{\nu \circ s, \log} = [\sigma_t^*e]_{\nu \circ t, \log}, \\ [M^{-1}]^* \mathrm{LogDR}_r &= [\sigma_s^*e]_{\nu \circ t, \log}, \quad \text{and} \quad [M]^* \mathrm{LogDR}_r = [\sigma_t^*e]_{\nu \circ s, \log}. \end{aligned}$$

Finally, we note that $[M]^*e = e$ and $\sigma_t = [M] \circ \sigma_s$, so that

$$[M]^* \mathrm{LogDR}_r = [\sigma_t^*e]_{\nu \circ s, \log} = [\sigma_s^*M^*e]_{\nu \circ s, \log} = [\sigma_s^*e]_{\nu \circ s, \log} = \mathrm{LogDR}_r. \quad \square$$

Remark 5.4. One can alternatively prove this theorem by appealing to the invariance of **Div** (see Section 4.2.1) under the action of M .

5.3 On the moduli space of curves

Here we translate the above results into the setting of [HPS19]. We fix non-negative integers g , n and a positive integer r . We choose r line bundles $\mathcal{L}_1, \dots, \mathcal{L}_r$ of total degree 0 on the universal

curve $\pi: C \rightarrow \overline{\mathcal{M}}_{g,n}$, for example of the form

$$\mathcal{L}_i = \omega^{k_i} \left(- \sum_{j=1}^n a_{i,j} x_j \right), \quad (5.3.1)$$

where $a_{i,1}, \dots, a_{i,n}$ are integers summing to $k_i(2g-2)$. The tuple $\mathcal{L}_1, \dots, \mathcal{L}_r$ defines a morphism

$$\Psi: \overline{\mathcal{M}}_{g,n} \rightarrow \mathfrak{Jac}^r,$$

and we write

$$\mathrm{LogDR}(\mathcal{L}_1, \dots, \mathcal{L}_r) = \Psi^* \mathrm{LogDR}_r \in \mathrm{LogCH}(\overline{\mathcal{M}}_{g,n}),$$

and

$$\mathrm{DR}(\mathcal{L}_1, \dots, \mathcal{L}_r) = \nu_* \mathrm{LogDR}(\mathcal{L}_1, \dots, \mathcal{L}_r) \in \mathrm{CH}(\overline{\mathcal{M}}_{g,n}).$$

Remark 5.5. Note that $\mathrm{LogDR}(\mathcal{L}_1, \dots, \mathcal{L}_r)$ is just the product of the classes $\mathrm{LogDR}(\mathcal{L}_i)$ for $1 \leq i \leq r$; this is *not* in general the case with DR in place of LogDR.

THEOREM 5.6 (DDR is tautological). *Suppose that k has characteristic 0. Then $\mathrm{DR}(\mathcal{L}_1, \dots, \mathcal{L}_r)$ lies in the tautological subring of $\mathrm{CH}(\overline{\mathcal{M}}_{g,n})$.*

Proof. For $1 \leq i \leq r$, define a codimension 1 class

$$\eta_i := \pi_*(c_1(\mathcal{L}_i)^2) \in \mathrm{CH}(\overline{\mathcal{M}}_{g,n});$$

these are of codimension 1 and hence tautological, so that $\mathbb{Q}[\eta_1, \dots, \eta_r]$ is a subring of the tautological ring T of $\overline{\mathcal{M}}_{g,n}$.

Pulling back, Lemma 5.2 implies that $\mathrm{LogDR}(\mathcal{L}_1, \dots, \mathcal{L}_r)$ lies in $\mathbb{Q}[\eta_1, \dots, \eta_r]^{\mathrm{log}} \subseteq T^{\mathrm{log}}$. Now T is tectonic by Lemma 3.20, and so $\mathrm{DR}(\mathcal{L}_1, \dots, \mathcal{L}_r) \in T$ by Lemma 3.19. $\square$

THEOREM 5.7 (GL($\mathbb{Z}$)-invariance of DDR). *If $M \in \mathrm{GL}_r(\mathbb{Z})$ and $M[\mathcal{L}_1, \dots, \mathcal{L}_r] = [\mathcal{F}_1, \dots, \mathcal{F}_r]$, then*

$$\mathrm{DR}(\mathcal{L}_1, \dots, \mathcal{L}_r) = \mathrm{DR}(\mathcal{F}_1, \dots, \mathcal{F}_r).$$

Proof. This is immediate from Theorem 5.3. $\square$

In the case $r = 2$, this recovers [HPS19, Theorem 1.2].

ACKNOWLEDGEMENTS

We are very grateful to Younghan Bae, Lawrence Barrott, Samouil Molcho, Giulio Orecchia, Rahul Pandharipande, Dhruv Ranganathan, Johannes Schmitt, Pim Spelier, and Jonathan Wise for numerous discussions of double ramification cycles on Picard stacks and logarithmic Chow groups. The idea of extending the multiplication formulae in [HPS19] to a $\mathrm{GL}_r(\mathbb{Z})$ -invariance property came up in a discussion with Adrien Sauvaget, and was further developed at the AIM workshop on Double ramification cycles and integrable systems.

The first-named author is very grateful to Alessandro Chiodo for many extensive discussions on computing the double ramification cycle on blowups of $\overline{\mathcal{M}}_{g,n}$, which provided key motivation and examples.

We are both very grateful to the anonymous referee for their thorough reading of the paper and very helpful suggestions. In particular, the main idea of the current proof of Theorem 3.8 was suggested by the referee, after they noticed some serious gaps in our previous attempt at a proof.
